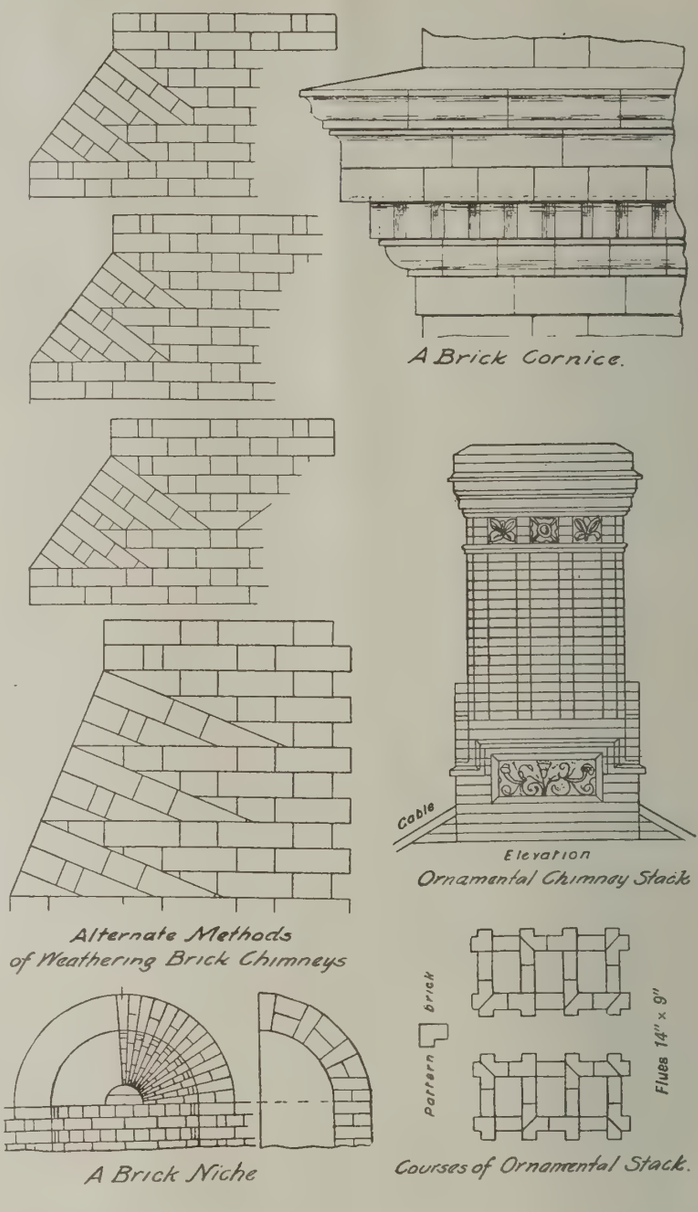
Good materials in the hands of poor or careless builders will so far deteriorate their actual value as structural materials from almost any point, that their relative value in this respect is reduced a hundred per cent. While this is true, it is also true that moderately fair materials in the hands of expert workmen can be made far more valuable, even surpassing in merit the better qualities when in the hands of the former class. This is a fact that should not be overlooked by all classes, both manufacturers, architects, and contractors. Each one is vitally interested in not only having the best possible clay products obtainable, but there is equally as much concern as to the ability of the men who undertake to construct the buildings with the various clay building materials.



Despite the ever-increasing number and kinds of structural materials, brick, and kindred clay building materials, have not only kept abreast of the increase, but have actually greatly increased in demand. There has been a reason for this, and one of the most notable causes in this respect has been the fact that there are so many clay commodities possessing more than ordinary qualities to withstand fire. Under this head comes fireproofing, as a leader, then terra cotta, flue linings, firebrick, vitrified brick and common brick. These are a few of the many specials, manufactured from clay. The list will not only compare favorably with any list of other structural materials, but will actually surpass it.

The public appreciate the simple fact that there has been hundreds of years service in clay building materials, and that they have withstood the most severe tests, which time alone can engrave on the durability of such commodities. In all these years there has been an upward tendency, and a striving for a higher quality, and a forward march toward the goal of fire resistance and durability under all trying tests. Had burned clay commodities not been able to withstand these time tests, had they been found failing in the crucial trials that the public has demanded, then today we would see a notable retrogression, and not the onward march that has been so noteworthy in the past few years.

How to increase this voluntary approbation should be the highest and foremost aim of the manufacturers of all kinds of clay commodities. They should be encouraged to fight for higher quality, for more enduring materials, for better quality in all that they essay to do. If their equipment is not of the best, and their help of the kind that is a drawback to their more notable achievements, then they should root out these cankers, and start afresh to gain new laurels for themselves and their industry.

The increasing call for fireproof structural materials should act as an incentive to spur them on to higher things. They must understand that while the construction work itself is too often a factor that is detrimental to the cause of the proper development of the fireproof demand, that they should not on this account, become lax in their efforts to improve the conditions that will make for a more trustworthy product from their own plants.

EXAMPLES OF BRICKWORK

NEW BOOKS RECEIVED

(Notice—All books noticed in these columns may be obtained from this office at Publishers' prices. All postage or express prepaid. Money and address must accompany all orders.)

THE LAW OF CONTRACT. VOL. I.—By Alexander Haring, C. E., LL. B., LL. M. Member of The American Society of Civil Engineers; Professor of Bridges and Railway Engineering, New York University; Member of the American Society of Engineering Contractors; Attorney and Counselor at Law.

Bound in Buckram—hard covers. Over 518 pp. Published by The Myron C. Clark Publishing Co., Chicago, Ill.

This will certainly prove a useful work for engineers and engineering students and in fact for all contractors in every line of business. The idea of the work seems to be the presentation in a condensed form, a text of the law of contracts in every form and to give the general theory of the subject as taught in the law schools—while yet evading the reading of endless cases, and as the author states, to give the student an understanding of the subject, sufficient to guide him in meeting the legal phases of whatever branch of engineering he may be engaged in.

The Law of Contract, as presented to the majority of engineering schools at the present time, consists of half a dozen lectures, delivered by an attorney, who aside from these lectures does no further lecturing or teaching. The result is what might be expected, the engineering student graduates with practically no knowledge of the subject. This text is intended for use as a recitation course, which may be supplemented by occasional lectures given by experienced professors of engineering. But, where such advantages are not available, a student may get a fair knowledge from this volume where precedents and the letter of the law are fairly set forth. Indeed, building contractors as well as engineering contractors will find in this work abundant material to set them right in case of doubt, as to the legality of any contract they may have in hand. No building contractor's office can be fully equipped without a copy of this book on its shelves.

METAL WORK AND ETCHING.—By John D. Adams. A complete handbook for art metal workers, giving every detail for making a great variety of useful and ornamental objects, such as book ends, desk sets, arts and crafts jewelry, hinges, drawer pulls, paper knives, letter openers, match boxes, tie and pipe racks, pad corners, etc.—fully illustrated; 96 pp. Well bound in cloth. Size, 5x7. Price, post paid, 25 cents. Published by Popular Mechanics Co., Chicago.

This is one of the series of hand books on Industrial subjects that this company is publishing from time to time and which is proving a great success among amateur and other workers in wood, leather, brass, copper and other metals. We have reason to believe that the sale of these work manuals is very large and meets with considerable favor by all people, of both sexes, who practice amateur work in any of its forms. The authors of these books are mostly practical men who have a thorough knowledge of what they are talking about, and who have the knack of conveying to their readers their ideas in the simplest and plain every day language. It is this quality that makes these manuals so popular.

The William T. Comstock Company of New York City, publishers of The Architects' and Builders' Magazine, announce that the name of the journal will be, after the present issue, Architecture and Building. This is the original name of the magazine when first established in the early 80's, and which did good service for the Architectural and Building world. We congratulate the publishers on the change of name, and hope adequate success, in every respect, may follow.

BUILDING TRADES INTERESTS IN THE COURTS

Technical violations of a building contract, which the contractor corrects on his attention being called thereto, are not "breaches," within the contractor's bond requiring notice to the surety of breaches of the building contract.—Lazelle v. Empire State Surety Co., 109 P. (Wash.) 195.

The mechanic's lien statute does not authorize a personal judgment against a wife for the price of material furnished to her husband under a contract with him and used by him in improving her property.—Robert Garrett Lumber Co. v. Loftus, 109 P. (Kans.) 179.

Where a wrecking contract provided that plaintiff was to remove a certain building "at once," and others at specified times, the words "at once" meant within such time as was reasonable under the attending circumstances.—Wetter v. Kleinert, 123 N. Y. S. 755.

The surety on the bond of a building contractor, providing for notice to the surety of breaches of the contract by the builder, may not complain of failure to give notice of breaches occasioning no loss to the owner; the surety showing no injury from the omission. —Lazelle v. Empire State Surety Co., 109 P. (Wash.) 195.

A contract to furnish materials for a building on leased property was sufficiently performed when the materials were furnished and put into the building, though the premises were not owned by the person contracting for the erection of the building.—Chelmsford Foundry Co. v. Shepard, 92 N. E. (Mass.) 75.

A building contract having provided that, in case the owner should be compelled to take charge of the building and finish the contract, the necessity for which was to be determined by a certificate of the architects, the cost of completion should be audited and certified by the architects, and such audit and certificate should be conclusive on the parties, the certificate of cost is admissible against the surety on the contractor's bond to prove the damages to the owner from the contractor's breach.—Lazelle v. Empire State Surety Co., 109 P. (Wash.) 195.

Where work is stopped on plans of an architect before they are completed, generally speaking, he is entitled to pay for services rendered, but it is otherwise when a condition of his original employment is that the plans shall be for a house not to cost more than a certain sum, and the change in plans is made upon the same condition, and an agreement to pay for extra work caused by the change is with the understanding that the plans, when completed, are to provide for a house costing not to exceed the sum as originally contemplated.—Hullmuth v. Benoist, 129 S. W. (Mo.) 257.

The mechanic's lien law (section 6244, Gen. St. 1909 [Code Civ. Proc. Sec. 649]), allowing a lien on a married woman's real estate for material furnished to her husband under a contract with him and used by him to improve such property, does not violate the mandate of the Constitution (article 15, Sec. 6) that married women shall be protected in acquiring and possessing property separate and apart from their husbands, or conflict with the married women's act (section 4872, Gen. St. 1909), providing that the separate estate of a married woman shall not be subject to the disposal of her husband or liable for his debts.—Robert Garrett Lumber Co. v. Loftus, 109 P. (Kans.) 179.

In a consolidated action by a contractor for the balance due on a building contract, and against the contractor because of the collapse of the structures, a charge that if the jury find that the contractor was to construct the structures under certain plans and specifications, and upon completion the structures gave way and became unfit for the use they were intended, then the contractor would be liable, etc., was properly refused, as incomplete, for failure to state that the giving way of the structure was due to failure to comply with the plans and specifications, and failure to state that the owners were free from fault.—J. W. Bishop Co. v. Curran & Burton, 76 A. (R. I.) 275.

In an action on a wrecking contract, a contention by defendant that the contractor was personal, and that plaintiff broke the contract by selling the building materials to other parties, who were to wreck the buildings and remove the materials, was untenable, since the work was not necessarily to be done by plaintiff in person, and, there being no assignment of the contract by plaintiff, his agreement with the parties to whom he sold the building material simply made them subcontractors in the work of wrecking, and the contract between plaintiff and defendant still remained, for the enforcement of the rights and duties of each other.—Wetter v. Kleinert, 123 N. Y. S. 755.

Defendant, S., after having conducted a store for some years under the style of S. & Co., had it incorporated in February, 1898, as the S. Company, of which he became president and secretary, and to which the firm property was transferred. The corporation decided to erect a new building on the premises which it leased, and at the request of its architect the plaintiff submitted to him a proposal to furnish certain material for the building, "all as per blue print submitted for building for Mr. S." At defendant's request, plaintiff's agent had an interview with defendant and the architect, at which plaintiff's agent consented to reduce the price for the material, which was noted on the written proposal, which was before the parties, and they made an oral agreement by which the plaintiff was to furnish the material required for the building and as called for by the architect's plans, etc. Plaintiff's agent did not then know that the defendant's business had been incorporated, and defendant made no mention thereof in their interview, but acted throughout as if contracting for himself individually; but the evidence showed that, so far as defendant had any intention, he intended to contract for the corporation. Held, that if defendant's conduct misled plaintiff's agent, so that he was justified in believing as a reasonable man that defendant contracted for himself, and not as agent for the corporation, defendant will be bound personally by the contract, and under the circumstances he was so bound.—Chelmsford Foundry Co. v. Shepard, 92 N. E. (Mass.) 75.

There can be no valid judgment of foreclosure of a materialman's lien for material furnished to a contractor upon the real estate improved with such material, in the absence of a valid judgment in favor of the materialman against the contractor for the price of such material. In a suit for the foreclosure of such a lien, where no personal judgment is sought, and the petition fails to allege that the plaintiff has a judgment against the contractor, and where the contractor is not a party to the foreclosure suit, it is erroneous to refuse to dismiss the petition on general demurrer.—Baldwin v. Shields, 67 S. E. (Ga.) 798.

A provision in a construction contract, providing for the allowance of additional time for completion in the event of delays from certain causes, but that no extension should be made unless a claim was presented in writing at the time of the delay, when the owner's superintendent should certify the additional time to be allowed, but permit the contractor to appeal from such award to arbitrators selected as provided, was not contrary to good morals or public policy, even if it made the owner's superintendent the final judge as to the time allowed as extensions, his award being binding if not made through fraud, mistake, or made arbitrarily.—Thompson v. St. Charles County, 126 S. W. (Mo.) 1044.

PATENTS.

The following list of recent patents and trademarks relating to building interests is especially reported for THE NATIONAL BUILDER by Wm. G. Henderson, solicitor of American and foreign patents and trademarks, Norris building, 501 F street, Washington, D. C. A copy of any of the United States patents will be furnished by him for 25 cents.

978,588. Shutter manipulator and fastener. J. W. Huntley, assignor to R. T. Marsh, Rockhill, S. C.

978,781. Window-glass setting gauge. E. S. Rhoads, Kansas City, Mo.

978,654. Floor surfacing and polishing machine. Peter Sass, San Francisco, Cal.

979,285. Reinforced concrete construction. John Gilligan, Nebraska City, Neb.

978,908. Excavating apparatus. Wm. J. Leary, assignor to W. J. Leary Manufacturing Company, Jersey City, N. J.

979,910. Shutter operating and fastening device. Chas. W. Adams, Putney, Vt.

979,913. Building-block. J. M. Ault, Decatur, Ind.

980,031. Sash-cord pulley. H. G. Boight, assignor to Russell & Erwin Mfg. Co., New Britain, Conn.

979,614. Floor-surfacing machine. Wm. E. Warner, Houston, Tex.

983,115. Floor and ceiling plate. A. J. Beaton, assor. The Beaton & Bradley Co., New Britain, Conn.

983,046. Interior mold or form for concrete structures. F. S. Graef, New York City.

983,011. Locking device for emergency exit doors. H. G. Boight, assor. Russell & Erwin Mfg. Co., New Britain, Conn.

982,916. Comb-cover for corrugated roofs. Wm. E. Williams and K. Roth, Terre Haute, Ind.

983,474. Transom lift. E. E. Bell, assor. Concealed Transom Lift Co., Glen Ridge, N. J.

983,681. Hollow fireproof partition sliding door for fire-walls. R. W. E. Buttlar, Columbus, Ohio.

984,132. Device for cutting slits in brick walls. H. Geyer, Munich, Germany.

984,216. Framing for concrete and cement constructions. W. Henderson, Cleveland, Ohio.

984,034. Cellar-door construction. H. C. Seipp, Coraopolis, Pa.

984,993. Mold for forming concrete silos. C. A. Anderson, St. Charles, Ill.

987,706. Floor scraper. S. Drew, Rochester, N. Y.

988,277. Reversible window. Wm. H. Meizel and J. L., York, Nebr.

987,819. Building block. Wm. H. Osburn, Kokomo, Ind.

988,326. Metal reinforcement for building purposes. H. Ferree, San Francisco, Cal.

989,328. Tiling fo roofs. DeWitt W. Buchanan, Chicago, Ill.

989,344. Building block. E. J. Forbes, Revere, Mass.

989,016. Fireproof building floor construction. E. V. Johnson, Chicago, Ill.

989,219. Hinge construction for doors. R. G. Winter, Milwaukee, Wis.

989,830. Reinforced concrete construction. Fred A. Berne, Birmingham, Ala.

990,029. Fire escape. A. H. Borden, New Bedford, Mass.

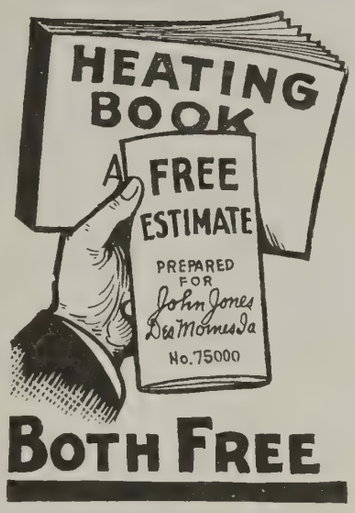
989,564. Artificial stone building block. J. Buhler, Zurich, Switzerland.

990,119. Building block. P. D. Diamond, assor. Diamond Concrete Mchy. Co., Chicago, Ill.

990,151. Metal door. Robt. D. Mayo, Grand Rapids, Mich.

989,646. Combined door hanger. A. E. Rupp, Chicago, Ill.

990,437. Concrete block mold. J. Hartley, Gobleville, Mich.



990,358. Emergency exit-door lock. P. W. Hodgkinson, assor. Caldwell Mfg. Co., Rochester, N. Y.

990,750. Device for locking the doors of emergency exits. O. Kublanck, Wittenberge, near Potsdam, Germany.

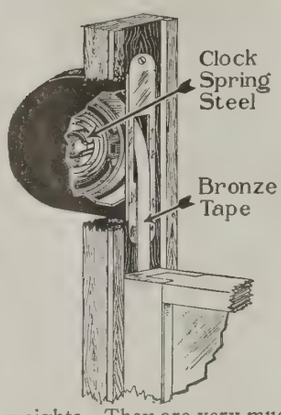
990,299. Reinforced cardboard and roofing plate. H. Schlisske, Musterlagke, No. 85 Hanover, Germany.

TRADE REVIEW

HOT WATER HEATING.

Not so very long ago, the coming of winter meant bringing out the old "base burner" from the woodshed to occupy the greater part of the parlor. Possibly a similar process took place in the dining room. Night and morning meant carrying coal and ashes through the house. But not even a "turkey wing duster" will clean up all the muss on the carpet nor will the zinc sheet prevent a hot coal burning a hole in the carpet and rug. In many homes every morning meant starting up grate fires in one or more rooms with the attendant labor of chopping up wood, etc., for the cold months.

The introduction of hot water heating was a great step forward toward proper heating of homes. From the discomfort of a local heat from a fireplace (a great part of which went up the chimney) there was the location of radiators under the windows, where the greatest cold came in. Instead of a draft from the window to the fireplace there was the gentle diffusion of heat throughout the room. In place of having a stove in the center of the room taking up the best part of the room, the radiator occupies only a small space in the most unobtrusive manner. Instead of lugging coal up from the basement or outside shed, the coal is piled within easy reach of the heater. Instead of one or two rooms unduly heated and the rest icy cold, the whole house is now evenly heated. In fact so many are the advantages of hot water heating that one who is accustomed to it cannot appreciate the discomforts of the early methods of heating.



Ready to Ship.

Anticipating the demand for hot water heating for residences, the Andrews Heating Company of Minneapolis, perfected a system by which they could supply complete heating plants in such shape that they could be sent to the job and erected by such labor as was available. Suitable erection plans are sent and all the piping cut to the proper lengths in such a way that no cutting and threading pipe on the job is necessary. A boiler of their own manufacture is used, which the Andrews Company claim is more economical, requires less care and is easier to clean. The directions which they send are so complete that there is little chance to go wrong in the installation. It is only necessary for the prospective purchaser to send a sketch, showing the sizes of the rooms, doors, windows, height of ceilings and general construction and their engineers will prepare an estimate showing the cost of the entire plant at your station, including Boiler Fitting, Piping, Radiator, Expansion Tanks, Regulating Safety Valve, Packing, Bronze, Brushes, etc., in fact everything necessary to complete the job.

On account of the peculiar nature of a heating plant, it is frequently impossible to tell if a plant is satisfactory until it is up against cold weather. A very little heat may suffice for an ordinary spring day when there is only a chill in the air, but a real fire is necessary when it is down to zero and a blizzard raging outside. To provide for this, the Andrews Company give every customer a 360-day Free Trial Guarantee Bond, which allows the trial through the entire winter.

Closely allied to the heating system are the systems for plumbing, water supply and sewage disposal. The Andrews Company design systems for this purpose on practically the same basis as outlined for the heating. As it is more than likely that the Andrews Company can direct the prospective purchaser to a home near him where their systems are in use, they wish everyone contemplating building or putting in any of the systems mentioned above would write for their 72-page book, describing the various systems in much more detail than can be given in these columns. This book is sent free by the Andrews Heating Company, 1188 Heating Building, Minneapolis, Minn.

FIVE MILLION PULLMAN SASH BALANCES SOLD.

The Pullman Mfg. Company, Rochester, N. Y., have made and sold, and there are in use today, over 5,000,000 of their Automatic Sash Balances.

This goes to show that the old fashioned cord and weight for windows is doomed. The Automatic Spring Sash Balance has every advantage over cord and weight, for it is self-contained, neat in appearance and requires no pockets or box frames as cords and weights do.

The Pullman Sash Balance is so constructed that the tension of a spring exactly balances the weights of the sash. The window may be raised and lowered with the greatest facility. The sash will stay wherever it is put with no more tendency to raise and fall of its own accord than with cord and weight.

Pullman Sash Balances cost practically the same to install as cords and weights. They are very much more durable, for the bronze tape which supports the weight of the sash is practically indestructible, and everyone knows how long steel clock springs last.

The Pullman Mfg. Company inform us that notwithstanding the fact that there are now over 5,000,000 of their Balances in use, and that most of the repairs must come from them, the total new tapes supplied do not amount to 100 a year, and most of these new tapes are called for when some careless person in setting a sash or removing one, has accidentally put a kink in the tape.

Architects and builders who hesitated to use the Pullman Sash Balance when it was first put on the market because of a feeling that it might not prove durable, have long since discarded this idea, for experience has shown that no other item of builders' hardware has more lasting qualities than the Pullman Sash Balance.

BUILDERS' HARDWARE.

The National Manufacturing Co., Sterling, Ill., have just issued their 1911 catalogue of Builders' Hardware. Since issuing their last catalogue they have completed and occupied a large addition to their plant. The floor space now covers some 100,000 sq. ft., or approximately two and a half acres.

While making a complete line of regular builders' hardware, the attention of the contractors and builders are centered on their barn door hangers and fittings, sliding door hangers, and special ventilating sash locks, all of which display remarkable ingenuity and are particularly adapted to their purpose.

Contractors and builders will find much more of interest in the catalogue than is indicated above, and we are advised that a copy will be sent on request.

THE WEBER WAX POLISHER AND SANDER

There is great demand for a small wax polisher and sander, if it is handy and effective.

Knowing this, Mr. John F. Weber, who has made almost a life study of contractors' needs, has perfected a polisher on an entirely new principle.

It is composed of three castings, three screws and a handle. The weight is separate and, when a thumb screw is loosened, the sandpaper block can be set at any angle. This gives as many different scraping surfaces as there are angles, and nearly doubles the life of the sandpaper. When the sandpaper does become worn out, a new sheet can be set in place in an instant.

When used as a wax polisher, a tough bristle brush of best quality fits into the place of the sandpaper block. The polisher is then ready for use. Special care has been taken to provide a weight just heavy enough to impart a fine finish without being hard to transport.

Both the sandpaper block and the brush fit into a clamping arrangement in such a way as to bring them flat and even on the floor. This care has resulted in producing a true "lineless" finish all over the floor.

Besides using this polisher themselves, contractors find a ready sale for them. After finishing up a house, it is a simple matter to sell one to the owner, because its utter simplicity and handiness—with its superior work—speaks for itself.

Contractors are asked to write to Weber Mfg. Co., 661 71st Ave., West Allis, Wis., for complete particulars and prices on this polisher and on a number of other modern money-saving devices, including the famous Weber Double Acting Floor Scraper.

CAPT. JOHN SMITH.

A short narrative on the life of this distinguished traveler, whose romantic adventures are more or less traditionary. On the grounds that the statements of manufacturers are true, the biographer bespeaks consideration for his Smith story.

It is a readable piece of history and should appeal to every member of the Smith family, as well as historians, and incidentally the users of Carborundum. The booklet is sent free on application to the Carborundum Co., Niagara Falls, N. Y.

ASBESTOS "CENTURY" SHINGLES

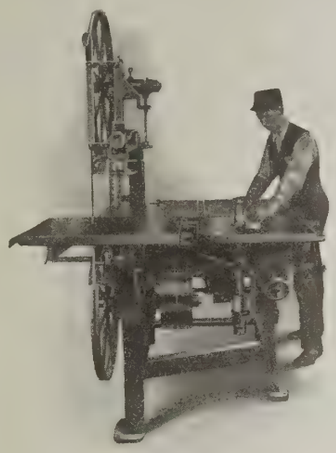
"THE ROOF THAT OUTLIVES THE BUILDING"

How long your client's pride in the building will last depends on how the roof holds out in the face of exposure to weather and storm. Long after the average roofing begins to show its age, cracked or warped, rotted or rusted, Asbestos "Century" Shingles are bright and fresh as new.

Asbestos "Century" Shingles are the first practical lightweight roofing of reinforced concrete—made of hydraulic cement with interlacing asbestos fibres—compacted by tremendous pressure.

Asbestos "Century" Shingle Roof—Residence of E. W. Twaddell, Devon, Pa.; E. S. Parson, Philadelphia, Pa., Architect; Simon Heister, Wayne, Pa., Contractor

They are weatherproof—fireproof—timeproof. Cannot rot, rust, crack, split or blister. They literally outlive the building—without repairs or painting.

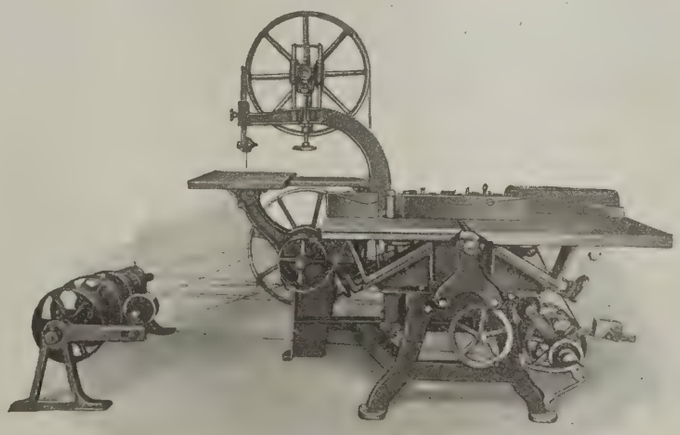


You can get Asbestos "Century" Shingles in shapes and sizes to fit any architectural scheme. Three colors—Newport (silver gray), Slate (blue black), and Indian Red. Ask your Roofer for new quotations. Write for booklet "K. & M. 1911."

The Keasbey & Mattison Company, Factors, Ambler, Pa.

PASTE THIS DOME ON LETTERS THAT YOU WRITE ADVERTISERS. IT WILL HELP.

A COMPLETE MACHINE SHOP EMBODIED IN ONE MACHINE.

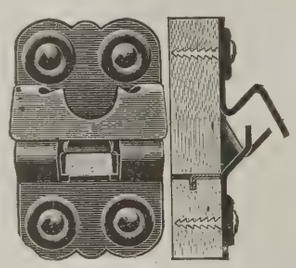


As in every other business competition among carpenters and builders is often keen, and the "little fellows" are often at their wit's end to figure out some scheme whereby they can bid on equal terms with their rivals and stand a better show of capturing the contract. After all it is only a matter of lessening the costs of production, and any proposition proving a means to this end should be thoroughly investigated.

But how to cut the costs! Various ways and means may be suggested, but the most prominent is that of cheaper millwork. Local planing mills can charge high prices and get away with it; you can not save anything in that direction. Clearly the only thing to do is to install your own planing mill; in other words, operate your own machine shop. This can be done by installing just one machine.

You may argue: "What's the good of one machine when I have a dozen different kinds of work to perform? Is it possible to use one machine as a band-saw, as a joiner, as a planer, as a mortiser and tenoner, as a sander, etc., etc.? I cannot afford to buy separate machines; furthermore, I have not sufficient floor space to install them or men to operate them."

Our answer to this argument would be to refer them to the No. 14 Famous Universal Woodworker, made by the Sidney Tool Co., of Sidney, Ohio, which does sixteen different kinds of work, each of which is performed by making a few simple adjustments. That carpenters and builders have been quick to realize the possibilities offered by this machine is proven by the fact that six hundred have been sold during the past two years, and that it is satisfactory is demonstrated by their all being in use today; not one has ever been returned or reported unsatisfactory.



The principle of constructing one machine to take the place of several is not new, but only one firm (the above named) have perfected it to the extent that it actually displaces over a dozen, without deteriorating from the quality of work to which the trade have become accustomed. Each of the various kinds of work can be performed as good, as quick and as clean on the Famous woodworker as on a machine built to do just one thing.

The No. 14 comprises the following sixteen machines: 27-in. Band Saw; 12-in. Joiner; Saw Table (with raising and lowering arbor); Single Spindle Shaper; Boring Attachment (arranged on special boring spindle); Pony Planer; Tongue and Pole Rounder; Hollow Chisel; Mortiser; Single End Tenoner; Drum Sander; Disc Sander; Knife Grinder; Emery Grinder; Band-Resaw; Spoke Tenoner; Rim Borer and Wheel Equalizer; Adjustable Felloe Rounder.

Consider the advantages of this method. Consider that you are doing your own millwork in your own shop, free from the delays and high charges of planing mills, putting their profits in your own pocket, and cutting down production costs that much. And remember there are no machines lying idle, practically no extra floor space required, no high-priced labor to pay, as anyone can operate the Famous. The Sidney Tool Co. will gladly send their catalogue, prices and terms upon request. Further information is given in their advertisement in this number.

WATROUS "SAFETY" SASH HANGERS.

The E. L. Watrous Mfg. Co. of Des Moines, Iowa, are offering to the trade the new No. 18 Safety Sash Hanger, as shown in the accompanying illustration. The makers claim for it the following points of superiority.

1. Always works perfectly. Impossible to set it wrong.
2. Quicker and easier to set, saves labor and money for carpenter and householder.
3. Will not blow off or be dropped by children or careless servants. The projecting guard will not let the sash come off till it is pushed out about half arm's length, where a little lift and pull unhooks it easily.

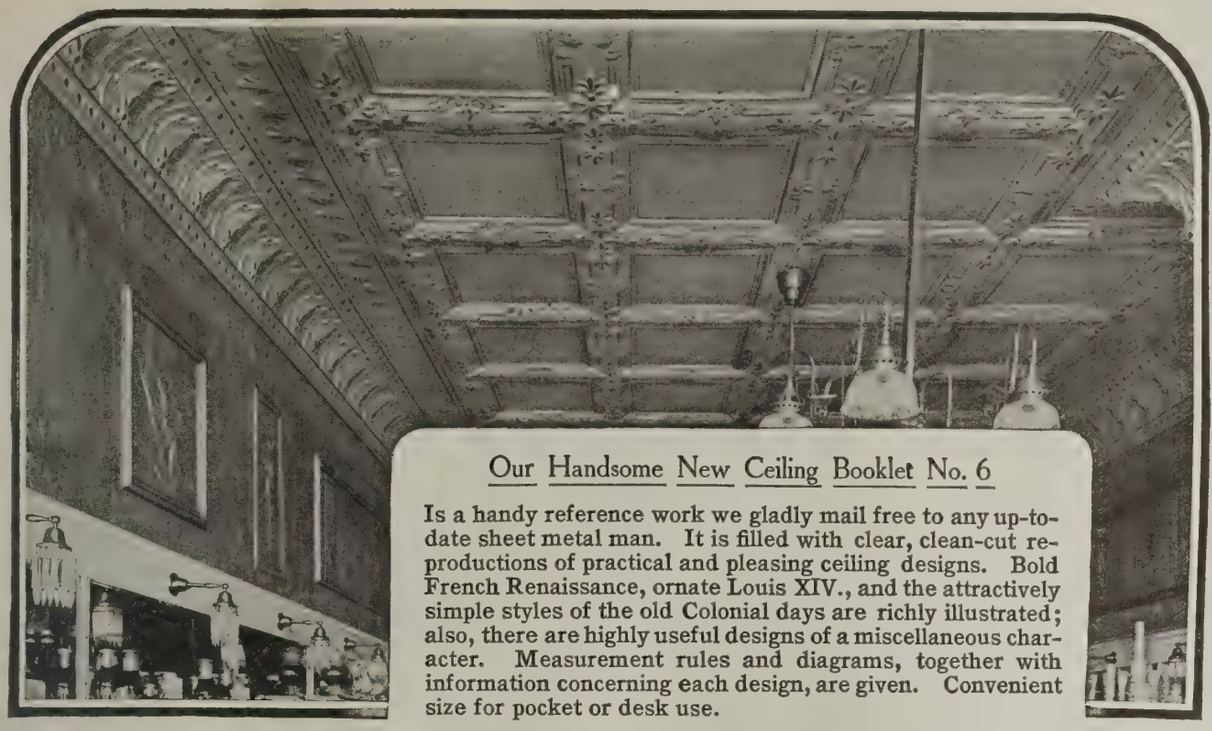
This hanger is packed with barbed car nails instead of screws. Nine carpenters out of ten drive the screws on these jobs with a hammer anyway, and a barbed nail will hold more than a driven screw, besides being easier to drive straight, and less likely to split the wood.

The guiding lug which locates the lower section of the sash prevents mistakes and insures perfect working of the hinge.

Anyone familiar with the sash trade knows the weird mistakes even a good carpenter will make in hanging screens and sash, and how often angry customers will condemn a sash hanger as "no good" when it is only set wrong, perhaps even upside down. Full directions are printed on the wrapper of each set of the "Watrous No. 18."

METAL CEILINGS AND METAL CONSTRUCTION IN SOUTH AMERICA.

Advices have been received from South America of the progress of Yankee-made products in that section of the globe. Manufacturers have been able to secure a reliable line on the likes, dislikes and demands of the public as a result of the wide range of exhibits shown at the Railways and Land Transport Exhibition, held in Buenos Ayres, Argentine, last August.



As representatives of American, German and British manufacturers of all kinds of articles, Ritchie Hermanos y Cia reserved much space at the exhibition and an entire page of the weekly edition of the Buenos Ayres Herald was given over to a discussion of the articles.

Among those mentioned as taking a firm hold in Argentine and other South American countries were the metal construction specialties, the metal ceilings and the steel furniture made by the Berger Manufacturing Company of Canton, Ohio. One of the exhibits was a small railway station building erected to show the advantages of the metal specialties. Its chief feature was its framework of metal lumber, which is designed to eliminate timber from the frames of light buildings.

This was hailed as something new and highly advantageous by Argentine contractors and builders. This new form of quick and light building construction is made of steel pressed into various shapes to form joists, studs, rafters, channels and many other members in general use. All these parts have prongs projecting every four inches when it is desired to fix expanded metal lath, so that the troublesome process of wiring the lath is done away with, it only being necessary to clinch the prongs to hold the lath.

Part of the building arranged for the exhibit was finished in Portland cement, showing solid partitions and hollow walls, both with expanded metal lath. A part was left as a skeleton to show the details of construction.

The Argentine Company, Ritchie Hermanos y Cia, has been doing a big business among contractors and builders as the result of the display at the exhibition, while they have installed a great deal of metal furniture and contracted for metal ceilings in many public and private buildings, particularly in Buenos Ayres.

Our Handsome New Ceiling Booklet No. 6

Is a handy reference work we gladly mail free to any up-to-date sheet metal man. It is filled with clear, clean-cut reproductions of practical and pleasing ceiling designs. Bold French Renaissance, ornate Louis XIV., and the attractively simple styles of the old Colonial days are richly illustrated; also, there are highly useful designs of a miscellaneous character. Measurement rules and diagrams, together with information concerning each design, are given. Convenient size for pocket or desk use.

We will mail your copy tomorrow if your address reaches us by that time.

METAL CEILINGS.

The Edwards Manufacturing Co., of Cincinnati, Ohio, are sending out their 1911 catalogue of Embossed Metal Ceilings and Side Walls. They have recently completed extensive new factories with specially designed machinery, and are in a position to turn out work of the best grade in construction, quality and appearance.

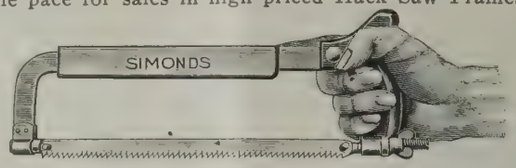
The advantage of Metal over other forms of decoration are many, most of them obvious to the thinking contractor and builder. It is healthier and drier than plaster and of course undergoes no risk of coming down accidentally. The saving on Fire Insurance is an item, while it is as ornamental as plaster or wood carving at a fraction of the cost.

In some locations it is necessary to clean the surface frequently and here the advantage of metal over wood or plaster is immediately apparent. As the metal takes paint readily any desired decoration may be applied. As a rule, it is recommended that a flat finish be applied as this will better bring out the detail of the stamping.

With every metal ceiling sold, the Edwards Company furnish a drawing showing the arrangement of the metal, which will enable the builders to erect the work without loss of time for laying out, fitting, etc.

While it is manifestly impossible to review all the advantages of metal over other forms of decoration a glance at the cut at the top of this article will convey an impression of the beauty of the finished work and the purity of style with which the designers have worked. The catalogue contains nearly 200 10x14 pages and shows a great variety of styles in plates, moldings, cornice, fillers, panels, wainscoting, etc., for every purpose. A great variety of finished rooms are shown including halls, stores, theaters, restaurants, banks, residence interiors, bath rooms, etc. The Edwards Mfg. Co., are placing their goods through local representatives as far as possible, and we understand that there are a number of excellent opportunities for contractors and builders to represent them in their locality.

INVESTIGATE THIS LEVEL.



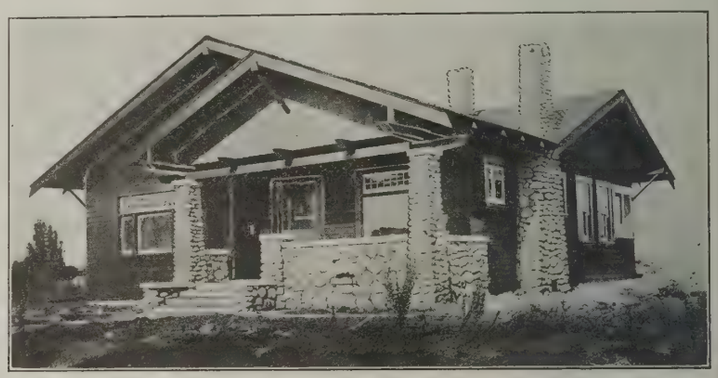
To those of our readers who are not already familiar with the merits of the Bostrom Level, or those who have been a bit skeptical on account of the very moderate price fixed by the manufacturers, we make a special request that a careful reading and consideration be given to the manufacturers' new announcement in this issue.

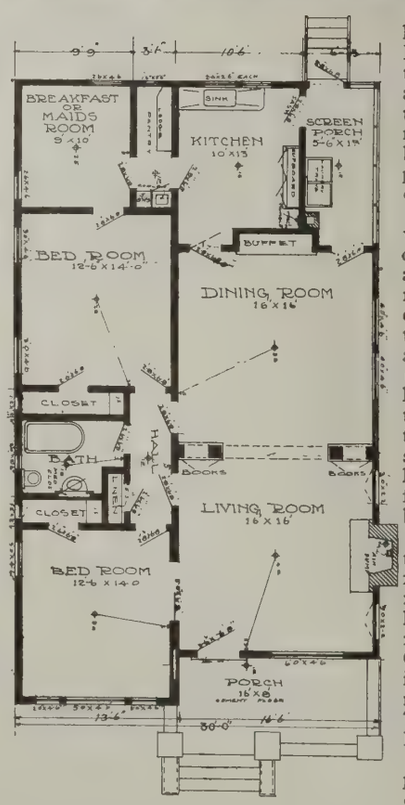
While a large number of our readers have already taken advantage of the opportunity of equipping themselves with one or more of these moderate priced, but thoroughly dependable Levels, there are those who have assumed since it has heretofore been necessary to pay much more to obtain a satisfactory Level, that it is still so, but the best proof of the incorrectness of this reasoning is the fact that those who have put their money in a Bostrom Level are the ones who have, by their unreserved and unqualified endorsements, established the fact that Bostrom's Improved $25.00 and $30.00 Builders' Levels accomplish all that is required or expected of Levels costing double the price, and in many instances meet individual requirements as completely as instruments costing several times as much.

You will find the manufacturers, Bostrom-Brady Manufacturing Company, of Atlanta, Ga., thoroughly reliable in their dealings, and we hope a large number of our readers will carefully read and accept their offer, as it is certainly as liberal as one could ask, the manufacturers assuming all risk, they requesting simply an investigation, thus allowing the instrument to make its own sale or not, you being the judge.

NEW HACK SAW FRAME.

The Simonds No. 41, Straight-Cut Hack Saw Frame, patented February 11, 1908, and just lately put on the market, is said to be setting the pace for sales in high priced Hack Saw Frames.





The straight-cut idea is decidedly novel and the Simonds' adaptation of that idea is one of the most simple and practical ones so far presented. The mechanic will readily appreciate the advantages of using a Straight-Cut Hack Saw Frame since with one hand he gets a better control over his work when using a Straight-Cut Frame than he had with both hands when using the old style frame.

The Simonds No. 41 is adjustable to blades from 8 to 12 inches long. It is manufactured exclusively by Simonds Mfg. Company, Fitchburg, Mass., and Chicago, Ill.

A CONVENIENTLY ARRANGED SIX-ROOM BUNGALOW.

By The Bungalowcraft Co., 407 Chamber of Commerce, Los Angeles, Cal.

This attractive little house has just been completed in Los Angeles at a cost less than $2,500, with oak floors and paneled wainscoting in the living room and dining room; built-in buffet, pressed brick mantel, large open fireplace, built-in bookcases, etc.

The exterior presents a well balanced and artistic combination of cobble stones and wood with a low pitched roof of simple but attractive design. The floor plan shows the arrangement of rooms and the many attractive and convenient features of the house. The endeavor throughout the planning of this house has been to save steps and labor for the housekeeper and a full measure of success has been attained.

As built in Los Angeles there was no cellar and no furnace, but this could readily be arranged if the house is built in a cold climate. The inside trim is of Oregon Pine, stained, except in the bathroom and bedrooms, where it is enameled. The walls are plastered with hardwall plaster and tinted.

The Bungalowcraft Company state that any inquiries regarding bungalows or bungalow building will receive prompt and detailed replies without charge.

ECLIPSE CONCRETE MIXERS.

In Bulletin Y 40, The Standard Scale & Supply Co., 1345 Wabash Ave., Chicago, illustrate a very complete line of Batch Mixers.

To be of practical use a Mixer must have wide usability. It should mix grout or dry plaster, top finish, or heavy gravel from the pit for massive foundation. For speed it must be loaded and discharged quickly, and above all, must be portable, for concrete must be mixed on the job under the eye of the superintendent, who has his other eye on the placing of the concrete. The experienced contractor will be quick to see the advantages of the Eclipse as shown and described in the above mentioned bulletin, which will be sent on request.

HOW THE MOTORCYCLE
INCREASED ONE CONTRACTOR'S EFFICIENCY

NOT long ago a prominent contractor (name and address on request) said to us. "I simply couldn't get along without my 'Harley-Davidson.' I find I am able to gather data, estimates, etc., much more quickly than I could when using my automobile. I have to-day several large contracts in different parts of the city which I could not superintend profitably without my motorcycle. It brings me the nearest to being in two places at once of any means of transportation I know of."

How many times Mr. Contractor, have things gone wrong because you were not there? How many times the cost of a good motorcycle have you lost by such absence? You can be there and five miles away to see a prospect and back in 15 minutes.

How many times have you found yourself unable to make the personal calls you should have? How many times have you found yourself tired out from long walks or car rides before the day's work was scarcely begun?

A Harley-Davidson motorcycle will do the road work of five horses and permit you to do the work of two men with less labor than at present. It means hot lunches at home, pleasant evenings, no tiring walk and long car delays.

Let us tell you how a Harley-Davidson will increase your earning power. Send for booklet 185.

HARLEY-DAVIDSON MOTOR COMPANY

707 L Street, MILWAUKEE, WIS.

"THE SILENT GRAY FELLOW"

Quick Transportation of Tools
Light Finishings and Other Materials

Carpenters, contractors and builders can save time by using an International Commercial Car. You know from experience that you require some means for the quick, cheap transportation of hundreds of "little things" that otherwise cause delay. Our International Commercial Car is what you need. It works whenever you want it to—in all weather, over all roads.

INTERNATIONAL COMMERCIAL CARS

never "tire," never go "lame," never "eat" except when in actual use. They travel three times as far as a horse, at less cost, with heavier loads. They take up less barn space, are clean, simple, strong and durable.

This car can also be converted into a double seated pleasure car if desired.

Write us for all the facts. You will be interested in what we have to tell you about International Commercial Cars.

GEORGE H. BISHOP.

The many friends of Geo. H. Bishop were shocked to hear of his sudden death on April 14th, at French Lick Springs, where he had gone to recuperate after an extensive Western trip. Mr. Bishop was president of Geo. H. Bishop & Co., of Lawrenceburg, Ind., and made friends, and retained them, through his genial disposition and kindly manner, which endeared him to all his acquaintances. While of a most kindly spirit, Mr. Bishop was at all times an exceedingly aggressive man. At an early age he left his home in Southern Indiana and made his way to Cincinnati, Ohio, where his first business experience was gained in the jewelry establishment of Duhme & Company. Late in the '80s he became connected with the National Saw Company, representing them on the Pacific Coast and in Canada and British Columbia, until their absorption by another manufacturer.

Mr. Bishop then purchased a factory at Lawrenceburg, Ind., the present location of the Bishop Saw Works. He was a 32nd degree Mason, Knight Templar and Shriner. The funeral services were conducted by Trinity Commandery No. 44 of Cincinnati, in the Scottish Rites Cathedral.

HARDWARE SPECIALTIES.

At the time the Wilcox Manufacturing Company, of Aurora, Ill., consolidated with the Richards Manufacturing Company of the same city, to be known as the Richards-Wilcox Manufacturing Company, the former company had in the press an extensive catalogue of their hardware specialties.

This catalogue, which is now in our hands, shows a very complete line of well known Wilcox Door Hangers, and also their specialties, among which are Bench Vises, Wrenches, Store Ladders, Grindstones, etc. Particular attention is called to their Auditorium Hanger, by means of which two rooms may be thrown in one, or a large room as quickly made into two or more. This hanger is used extensively in schools, churches, lodge rooms, etc.

Aside from making the goods of the materials best suited to their use, the most important qualities should be adjustability, that it may overcome inequalities in the floor, settlement, etc., and permanence, requiring no repairs or adjustments in the hardware itself, due to working loose or wearing unevenly. The appearance of the goods illustrated and described would indicate that the Richards-Wilcox Manufacturing Company had brought the goods to a high standard of perfection. A catalogue of all these interesting speciatlties will be sent to the carpenters and builders who write to the Richards-Wilcox Manufacturing Company, Aurora, Ill.

GALVANIZED WALL TIES.

The Niagara Falls Metal Stamping Works, Niagara Falls, N. Y., are mailing a folder descriptive of their 12-in. Galvanized Wall Ties. These ties are invaluable for stone and concrete block walls, where there is a danger of cracks or openings occurring in the walls due to faulty foundations or imperfections in mortar or laying. Every tie that is sent out from the factory is thoroughly well made, and the fact that many of the leading architects are including them in their specifications speaks well for the quality of the product. Concrete block walls have quite as much tendency to crack as brick walls, and probably more, and the ties, whether single or double width, properly placed and used in sufficient numbers are proof against cracks. Builders and contractors desiring samples should write the manufacturers, as they are glad to send samples free to any one interested.

INCREASING DEMAND FOR BRICK FIREPLACES.

The growing interest in brick mantels and fire places renders it imperative that the architect and builder should have close knowledge of the subject, for while nothing is less attractive than a crude arrangement of poor bricks poorly arranged, and called a fireplace, the sold dignity and elegant simplicity of a real brick mantel appeals to every person of good taste. Brick fireplaces were formerly thought only appropriate for clubs, hotels, large residences and other places where space and money were abundant. At present, many plans for moderate sized and cost homes are arranged for several brick mantels. The magazines devoted to home building have steadily created a strong desire for the right kind of brick mantels in a nation rapidly growing in culture as well as wealth.

The Bradford Pressed Brick Company of Bradford, Pa., have produced for sixteen years the highest type of face brick. Their reds gave the rich, warm color of the natural shale peculiar to that part of Pennsylvania. Their mantel catalogue shows a great variety of shapes and sizes in their moulded lines. The bricks are packed and marked and their laying so accurately described that no builder can fail to construct a perfect fireplace and mantel that will be free from defects, once seeming necessary in a brick fireplace.

The cost of the bricks, panels, moulding, returns, etc., for a complete mantel will vary from $23 to $56, and the setting can be done by any good mechanic. Correspondence is invited by this reliable company, whose product has been favorably known to the editors of THE NATIONAL BUILDER for many years.

MODERN INTERIOR TRIM.

In a recent number of the National Builder several arrangements were shown for utilizing the space of unused door openings. Frequently there is not room for a large pier glass without inconvenience somewhere, and it is with the purpose of supplying the want without the inconvenience that the Huber Builders Material Company of Cincinnati, designed the door shown herewith. As will be seen, the door simply has a large plate glass mirror in place of the wood panels usually furnished.

It is possible that to some, the grain in the wood panels and rails is preferable, but in many places, space is an item and the mirror door will usually be given the preference. The appearance is often that of an enlarged room while the usefulness of the mirror is apparent.

The door shown above is only one item from the 1911 catalogue of the Huber Building Company. This catalogue should be in the hands of every contractor and builder as there are many bargains and novelties listed. This catalogue is sent free by the Huber Building Company, Vine and Second Sts., Cincinnati, Ohio.

WOOD CARVINGS.

The great charm of wood carving, whether on a part of the structure or as applied ornament, has occupied the minds of the best artists for centuries. Until the introduction of high grade wood working machinery, the cost of this class of work was so high as to allow its use on only the most expensive work. At the present time, however, the improvements in processes of manufacture enable the cabinet maker, carpenter or builder to secure the highest grade of work at only a slight increase over the cost of the materials.

There are few concerns which have done more to improve methods of manufacture and bring the business to a commercial and artistic perfection, than the Waddell Manufacturing Company of Grand Rapids, Michigan. In their catalogue and revised price list No. 21 are shown over a thousand designs of wood carvings. Stair work, Newels, Ramps, Easements, Balusters, Mouldings, Ornaments, Grilles, etc., for practically every purpose in building or furnishing. There are grilles and pedestals for the house, knobs, rosettes, and scroll ornaments for furniture. By their improved methods they produce all the fine effects of handwork at machine prices. They also employ a staff of skilled designers and hand carvers, by which the designs of the architect may be carried out from either sketches or detail drawings. This service is only slightly more expensive than the machine work, and adds greatly to the individuality of the work.

The catalogue shows in photographic reproduction their stock patterns. From these can be seen the artistic perfection and beauty of detail of the carvings, and it is usually possible to make a selection particularly adapted to the work in hand. A charge of 15 cents to partially cover the cost of packing, postage, etc., will bring the book to any of the National Builder readers. Address the Waddell Manufacturing Company, 67 Coldbrook St., Grand Rapids, Mich.

Buy Saws Only When You Need Saws

But when you need them buy

SIMONDS SAWS

Pronounced SI-MONDS

This Saw is the Manufacturer's own brand saw; therefore note carefully the trade-mark which is on it. It is covered by the manufacturer's guarantee. It is vouched for by hundreds of Carpenters throughout the United States who during the past few years have slowly but surely become better acquainted with this saw. It is made of Simonds Steel, a steel manufactured exclusively for saws in Simonds' own steel mill.

Note the pronunciation of the name. Ask your Hardware Dealer for the Si-monds Saw. Each Saw packed in a separate case. This Saw is made especially for those who care to pay just a little bit more for the satisfaction of owning a superior article.

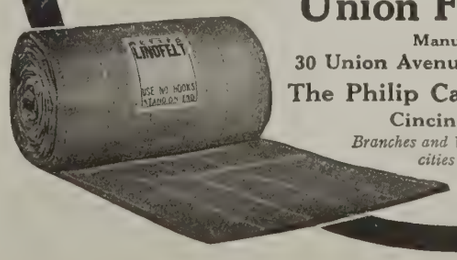
Sheath Your Houses With LINOFELT

Linen-Felt made from Flax-Fibre

38 Times More Effective Than Building Paper

BUILD houses that keep the outside *out* and the inside *in*, that keep *out* the cold of winter and the heat of summer, that keep *in* the warmth in winter and the cool in summer. Put up houses and buildings that keep out sound, the rooms of which are quiet and restful. Getting these features will add less than one per cent to the cost of your house, will add more than 40% to its comfort and living value and will effect a constant saving of 40% in all fuel bills. Architects, contractors and carpenters are the ones able to appreciate most the superiority of **Linofelt** because they know how unsatisfactory is ordinary building paper.

These Plans Show The Method



They show you clearly the practical and simple method of insulating walls and floors with **Linofelt**. Every carpenter, every builder, every architect realizes just what these little plans mean. They are keen to the advantages of building according to these methods. They know how important such efficient insulating of walls, floors, ceilings and partitions is to *all* classes of homes and buildings. We might emphasize residences, office buildings, hospitals, school buildings, stores, and buildings constructed for manufacturing purposes. These must have the uniform warmth in winter, coolness in summer and the quiet all the time that **Linofelt** insures.

Anyone who knows **Linofelt** immediately becomes enthusiastic about it—because it has so many delightful features. It is an insulating quilt. No other is as light as **Linofelt** cubical contents considered. It comes from the same source as linen. It is made from flax in the largest flax market in the world—Winona. It is odorless, chemically clean, as sanitary as a surgical dressing.

We have had made comparative tests of **Linofelt** and other sheathing mediums for sound deadening qualities. We will send them on request. The same sound heard 200 feet through ordinary building paper is heard only 2 feet away through **Linofelt.** Tests prove **Linofelt** more than 38 times as effective as building paper for all uses.

Let Us Place All The Data In Your Hands

Let us send you an attractive book for Architects, Contractors and Carpenters showing **Linofelt** in all forms, telling how it is made, showing and explaining plans and methods of using **Linofelt,** illustrated with excellent photographs of residences and buildings built with **Linofelt,** located in different climates. Let us send you this meaty book because it also tells in like manner of Lith Board and Rock Wool. Let us acquaint you with our Service Department, our own engineers, who have a world of experience in insulating work, who have pursued it under all sorts of conditions for a great many years, who are fully equipped and qualified to be of the greatest assistance to you in your work, whom you can consult at any time regarding any of your work *gratis*. Let us send you a **free** sample of **Linofelt** so that you can see it with your own eyes and feel it with your own hands and have a close realization of its extreme effectiveness, have a firm knowledge that it will do *more* than we claim it will do. Get the book, the service, the sample by writing to us today. **Please ask us for the name of the dealer nearest your home.**

Cassens Ideal Eaves Trough Takes Water Only

The Ideal completely overcomes the disadvantages of the old style open gutter. It satisfactorily catches and carries away the water that falls on your roof. Its use insures clean, healthful cistern water. Leaves, trash, gravel, etc., cannot enter it. Neither can birds build nests in it. Therefore it is never clogged. **Ice will positively not break down the trough**

A unique and important feature of the IDEAL is that it will not fill with snow and ice. When it sleets the small opening (about one-eighth inch) is quickly closed. This prevents the bursting of the trough, also of the down spout. When it thaws the ice melts, and the entrance opens automatically before the water from the roof reaches it.

The Ideal can now be erected with a Wire Hanger if face-board has mouldings.

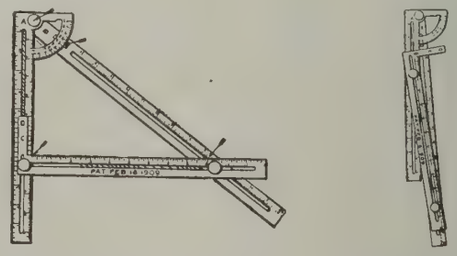
CASSENS MANUFACTURING CO., Edwardsville, Ill.

MOTORCYCLES FOR CONTRACTORS.

A noted writer speaking of the mistakes man in general is prone to make stated, "The average man's errors can be divided into two classes. The errors of commission and the errors of omission." Of these two with the contractors, the first is undoubtedly by far in the minority.

The average contractor of today has generally so thoroughly mastered his profession or has had sufficient experience "burning his fingers" to thoroughly convince him that contracts which call for things "he don't know" had better be left alone, therefore the average contractor's loss from "doing things wrong," due to lack of knowledge is small.



Errors due to omission, naturally cover by far the majority of contractors' losses. This is undoubtedly due to the small margins on contracts in general, combined with the natural ambition of the American contractor to "get along." Many contractors in the phraseology of the day "bite off more than they can chew." They bid on a number of contracts and fortunately or unfortunately, as the case may be, are awarded more work than they can personally supervise thoroughly. Then come the losses through omission. This or that goes wrong. Errors arise which before they come to the contractor's attention, have absorbed more or less of his margin. The writer personally knows two or three contractors whose annual losses would have made a fair start for a saving account. Obviously the easiest way to overcome or remedy this great source of loss must be one which will broaden the scope of the ordinary contractor's personal supervision. Many of the large contractors realizing this have purchased automobiles and found that by means of same, they can nearly double the amount of work they could formerly properly supervise. The original investment as well as the up-keep, however, has prevented many from adopting this method. To this, by far the larger majority, the motorcycle should prove a boon. The writer recently talked with one large contractor who stated that he had used horses, autos and finally the motorcycle. Now he uses the motorcycle entirely as he finds he can not only get around faster in crowded districts, but much more economically. He says in part, "I ride a —————— motorcycle made in Milwaukee. I don't know what the up-keep cost of the other machines may be, but I do know that my operating cost is but a fraction of a cent per mile, in fact, far less than my former carfare and I further know that my motorcycle has saved me its original cost time and time again. When I considered the purchase of a motorcycle, I looked at it from a purely business standpoint and sat down and figured it out. I estimated my time as worth $2.00 per hour and when I figured the hours a machine could save me—well, there stands my motorcycle.

"Now four of my carpenters and two of my masons have purchased machines and are living out in the suburbs, where rent is cheap. Although one of them lives nearly five miles away from his present work, yet he finds that the hour's nooning gives him ample time to run home and have a hot dinner. Each of them have a luggage carrier or rack right over their rear wheel to carry their tools on. The motorcycle brings me nearer to being in two places at once than any other mode of conveyance."

Here's food for thought, Mr. Contractor. Personally, I don't know whether this contractor was right or not, but I do know were I a contractor, I should most assuredly investigate.

THE A B C PROTRACTOR AND SQUARE.

Practically, the difference between an ordinary workman and a foreman is in the latter's ability to lay out the work. In carpentry, as in stone masonry, a knowledge of geometry and mathematics is usually necessary in order to accomplish some of the commonest forms in construction, and, while it is always convenient to have an understanding of the sciences, the ingenuity of modern designers has obviated the need of detailed technical training and enabled the mechanic who knows what he wants to do to perform the same operations mechanically as the technical man does with mathematics. An instrument of this character is the A B C Protractor and Square, made by the Crookston Tool Company, of Crookston, Minn.

This instrument, as seen by the cuts herewith, consists of three parts working together, the different pieces being lettered and figured to give the required results. It works on the principle of the right-angled triangle, and is capable of giving any of the cuts required on a building, no matter how intricate, and it will give the length of rafters, etc., as well.

This instrument, so simple that it is called a tool, is meeting with deserved success wherever introduced, and readers of THE NATIONAL BUILDER who are not already acquainted with it should investigate.

We understand that the Crookston Tool Company, who are placing this tool on the market, guarantee that it will do all they claim it will. Aside from the very complete directions which come with the tool, they are always willing to explain fully any point not perfecty clear to the user.

HERE'S THE LEVEL THAT'S ALWAYS RIGHT

Akron Eclipse Levels are dependable—always accurate—always right in every way—the kind a good workman wants and appreciates. They're as different from other levels as a dropforged hammer is from one that's cast.

The Akron Level is the pioneer among spirit levels—the one that introduced the idea of having two plumbs so that stock can be applied either end up. More improvements in spirit levels today are due to the Akron than any other source. Others have imitated, tried to equal, but without success.

For twenty-five years past

Akron Eclipse Levels

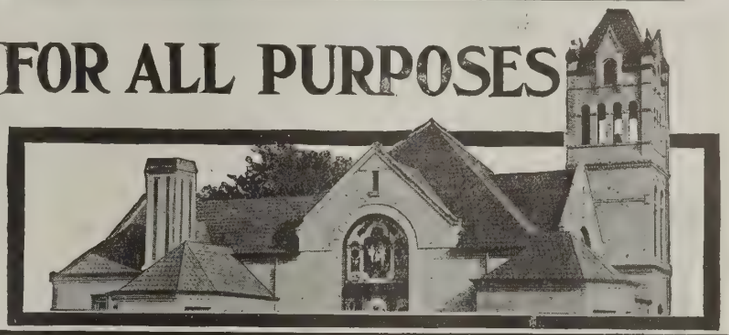
have been, and today *are*, the best spirit levels made. Thousands of skilled craftsmen in all parts of the world acknowledge the supremacy of the Akron.

The Akron has two exclusive and valuable features found in no other make—

1—Non-Breakable Double Spirit Tube
2—Easy Reading Feature

Unlike ordinary levels, the Akron Eclipse spirit-tube is set in an outer tubing of heavy steam-gauge glass, which is unbreakable with ordinary use. The *easy reading feature* consists of 2 silver lines around spirit tube, one at either end of bubble when it is in the exact center. This shows L-E-V-E-L or otherwise instantly, even in a dim light. No straining your eyes or getting out your spectacles when you use an Akron level.

Made in 33 styles and sizes for every purpose—some with 2 plumbs, some brass bound, but all with adjustable glasses. You'll find the one best adapted for your needs.



Ask Your Dealer

but if he or some other dealer in your town does not sell Akron Eclipse Levels, write us for catalog and prices. We'll fill your order direct.

Look for This Trade-Mark
It's the distinguishing mark of all genuine Akron Eclipse levels.

BAKER, McMILLEN CO.

FOR ALL PURPOSES

CORTRIGHT
Metal Shingles

What appeals to Carpenters and Builders about Cortright Metal Shingles is the fact that they have all the advantages of other forms of roofing combined; so that they do not have to adopt a special kind of roofing, and employ a special kind of labor for each different job.

Cortrights they can use for any style building, and can be laid by their own men, eliminating trouble and expense of employing special skilled workmen.

And best of all—besides these advantages he is able to overcome with them any kind of roof competition, for Cortrights are Fireproof, Stormproof and will outlast the building without needing repairs, and at the same time afford a far more handsome roof.

All these facts are illustrated and described in our catalogue "Concerning That Roof." It also shows how Cortrights actually look on all kinds of buildings. Write us for our proposition.

FLY ESCAPE SCREENS.

With the approach of the warm season we are again confronted with the "fly-question." In some parts of our country we have the question the year round, complicated by mosquitoes and other insects.

To a certain extent these can be kept out at the wnidow openings, but the opening doors allow enough to enter to make trouble for the susceptible. To get them out after once in is difficult as opening a door simply lets more in, and the ordinary driving out results in merely a stirring up and adding new blood.

To remedy this evil, and get the pests out after they get in,

The Chattanooga Screen Company make a clever device to be attached to old screens or incorporated in new ones. The ingenious construction seems to lead the flies to the "exit" and through the turnstile to the open air; with them goes the danger of contamination, disease and annoyance.

The Chattanooga Screen Co., Chattanooga, Tenn., make screens having this device and want to hear from everyone before ordering screens.

STYLE AND DETAIL IN SHEET METAL WORK.

The Empire Iron and Steel Company of Niles, Ohio, in their catalogue of Metal Ceilings and Sidewalls, shows a number of excellent designs of the French Renaissance, Louis XIV and Colonial periods. Fidelity to the detail of these periods is difficult in most classes of decoration, as the delicacy of the detail is easily destroyed by the necessary repetition. In the example shown in this catalogue, the technique of the artist is faithfully reproduced in the finished product, while the greatest attention is shown to the constructive detail in order to allow sufficient leeway for the mechanic when installing the work. Extreme accuracy is possible in the drafting room and possibly in the shop, but as a rule the workman installing the finished work meets unforeseen obstacles to clocklike precision in the installation, due to interference by other mechanics, avoiding other work, scaffolding, etc. To furnish plates, etc., to fit properly under these conditions, requires the experience which only comes with close intimacy with the details of construction, manufacture and erection.

We understand that the Empire Steel and Iron are well equipped to do this class of work.

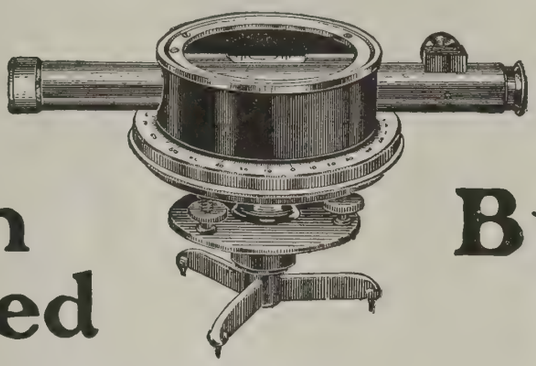
Rules for measuring surfaces are given in detail, so that no difficulty should be experienced in ordering. The prices also are given, making the work a ready reference on the subject. This catalogue, we are advised, will be sent free to interested readers of THE NATIONAL BUILDER and those contemplating the use of Metal Ceilings, by the Empire Iron and Steel Company, Niles, Ohio.

AN ADVERTISING CAMPAIGN IN THE INTEREST OF BUILDERS AND ROOFERS.

Builders and roofing contractors will be interested in the advertising for Asbestos "Century" Shingles, which the Keasbey & Mattison Company are running in "Country Life in America."

The campaign started with the December issue of this magazine, and will be continued monthly, the advertisers state.

Each advertisement shows one of the hundreds of handsome private and public buildings which are roofed with Asbestos "Century" Shingles, with strong text on the merits of this well-known roofing, and refers the interested reader to the nearest responsible roofer for estimates and quotations.



We reproduce on this page the illustration from the second of these announcements—showing the Communal Theater of Fiume, Austria.

Builders and roofing contractors who are not in touch with the Asbestos "Century" Shingle proposition will do well to write to the Keasbey & Mattison Company, at Ambler, Pennsylvania, and get into position to take advantage of the added demand that is sure to be created by this advertising.

EVERY CONTRACTOR

LARGE OR SMALL WOULD BUY A

Bostrom Improved Builder's Level

If he would just drop us a line to ship him one for inspection and approval. We say that because we have never known a Contractor, Builder, Architect, Surveyor, Civil Engineer, or even Instrument manufacturer to inspect a BOSTROM LEVEL who did not concede that **at the price** there had been nothing yet produced which would compare with the Bostrom in all the necessary essentials of a **simple, accurate, durable** and **throughly dependable** Level

Another thing, the Bostrom Level possesses means of adjustment for proving its accuracy, not surpassed by the highest priced Engineer's Level, and this principle is applied in such a novel and simple manner that even the inexperienced operator can **prove his work right on the spot,** and it can be done in a mere fraction of the time required to prove the accuracy of any other level, regardless of the price.

You have to examine the Bostrom Level to appreciate all of its merits, but the above feature alone makes sales on sight, and a sale always means a Bostrom endorser.

We back up every statement we make with a GUARANTEE of satisfaction or money back.

Our terms are cash with order, or shipment made C. O. D. SUBJECT TO EXAMINATION. Prices: No. 3, $25.00; No. 4, $30.00, f. o. b., Atlanta. Shipping weight 15 lbs., and complete outfit includes Level, Tripod, Graduated Hardwood Rod (not furnished by any other manufacturer without extra charge), Target and Plumb-bob, Trivet, and neat oak box for keeping Level when not in use. Eyepiece in No. 3 Telescope has magnifying power of 10 to 12 diameters, with sliding focus; and eyepiece in No. 4 Telescope has magnifying power of 18 to 20 diameters, with rack and pinion focus.

If you are needing Level at once, order direct from this article, as we do not even require you to guarantee express charges (and no other instrument manufacturer ever made such an offer). We don't hesitate to do it, as we have shipped thousands of Levels in that manner, and the enthusiastic endorsements of these purchasers gives us the unlimited confidence that the Instrument will please you. If you are not needing Level right away, write for full description and get acquainted with the Bostrom before buying. Bostrom's Levels are used and endorsed in every State in the Union, and are rapidly taking the place of instruments much higher in price, and you owe it to yourself to inspect the Bostrom before buying.

KEYLESS LOCKS.

It is easy to lock the door after the horse is stolen, but how much better to put a lock on before. And not only a lock, but a lock which is proof against the many failings of ordinary locks. Some locks are easily picked. Some get out of order and won't work when most wanted. Keys get broken, lost or mislaid. There has recently been placed on the market a lock which the manufacturers claim is proof against all these accidental annoyances. And at the same time offers perfect protection against all not inclined to be perfectly honest. The Dayton Keyless Lock Company make a number of styles of Keyless Locks suited to the finish of various styles and all embodying the principles of ease of operation and absolute protection. The lock is operated on such a simple system that a child can quickly open the door in the dark, while the combination can be changed in a few minutes should it be considered advisable.

The Dayton Keyless Lock Company, 804 U. B. Bldg., Dayton, Ohio, are sending convincing literature to all interested and are anxious to get in communication with men in the building field who will act as salesmen for them.

OF SPECIAL INTEREST TO BUILDERS.

The David White Company, 421 E. Water, Milwaukee, Wisconsin, Manufacturers of Surveying and Engineering Instruments, have perfected a high-grade Combination Level and Transit as illustrated in cut herewith. This Instrument is a saver of both time and labor, two items of importance to the Builder, and is an Instrument no Builder or Contractor can afford to be without. It can be used to plumb a wall, line up girders, lay stakes, grade streets, square buildings, etc., and will practically do the work of a Level and Transit as well.

It is constructed the same as our Improved Architect's Level, with a Telescope 12" in length and adjusted in the same manner as the larger Levels. The lenses are of the best optical quality, magnifying power about 25 diameters, object glass 1¼" and is provided with 4 leveling screws and clamp to spindle. The Y's have an improved locking arrangement, dispensing with the pin bolts. It has also a horizontal circle 4½" in diameter fitted to the upper end of the socket and turning readily upon it; the circle is graduated from 0-90 each way, and has a vernier to read to 5 minutes, which is screwed to the flange of the center. The Telescope is of good definition and is focused by rack and pinion. The eyepiece turns in a screw like manner to enable precise focusing of the cross hairs. The Tilting Level has an addition of an attachment by which sights of 45 degrees above or below the horizontal can be taken. This attachment is a small set of standards screwed into the center of the level bar and when not in use can readily be removed permitting the telescope to be set back in the wyes. The Instrument is supplied complete with Tripod, Trivet Sun-Shade, Plumb-Bob, etc. Write for Catalogue and Special Prices.

Where the Big Bargains Come From

Out from these great concrete warehouses come the greatest millwork and lumber bargains that the American market affords.

Our whole business revolves around the bargain idea. The present building season finds us better equipped than ever before to save money for contractors and builders: You will be amazed to see the big reductions on staple millwork and lumber of highest guaranteed quality.

New Bargain Catalog Ready

This catalog is in itself an immense exhibit of the finest building material on the market. It offers an almost unlimited variety of the latest styles in millwork of every description. Doors in all regular sizes and in scores of new and beautiful patterns and in various woods—veneered doors in Colonial, Mission, Craftsman and other popular styles—art glass doors in exquisite designs and colors—doors for every purpose. Windows to correspond with every style of door. Mouldings, inside finish, flooring, mantels, stair and porch material—everything that goes into any home, down to the very last detail. A bargain price and a guarantee of quality safe delivery and satisfaction on every item. Send for the catalog and see for yourself.

New Plan Books—Just Out

The new Gordon-Van Tine Book of Plans, prepared at a cost of over $5,000, is now ready for free distribution to carpenters and contractors. A complete and practical work that gives 32 designs for city, suburban and country residences, cottages and bungalows costing from $600 to $6,000. Also 12 plans for barn, dairy and cattle barns and other outbuildings. **This book keeps cost within original estimates,** for every plan has been proved again and again by actual construction.

The Plan Book will be mailed free on receipt of 10 cents in stamps or a dime to cover cost of packing and mailing.

You Are Invited to Visit Our Vast New Millwork and Lumber Plant

Although we conduct our business entirely by mail, we like to have carpenters and contractors visit our plant. Hundreds of them do this every year. Our warehouse is the busiest place in Iowa. Come and see us loading 22 cars at a time from our loading platforms, extending the entire length of the plant. Meet personally the men who stand behind this gigantic enterprise. The latch-string is always out.

THE JACKSON ALUMINUM LINE LEVEL

Is designed particularly to meet the requirements of all Mechanics in building construction, especially Bricklayers, Masons, Carpenters, Millwrights, Architects, and Cement Workers.

By using the Aluminum Line Level you can take Levels in one-half the time required by the old method of the Straight Edge.

This is possible because the Aluminum Line Level weighs only one-fourth ounce and is easily and quickly attached to a line. Levels thus taken are guaranteed to be accurate on a stretched line from one to forty feet. Besides, from its construction, it can be used as a Pocket Level.

This cut shows the Aluminum Line Level, including Attachment and 40-ft. line. Complete in Leatherette Case.

PRICE $1.00, POSTAGE PREPAID

It is especially adapted for laying out foundations for buildings. It will do the work no other level will do. For sale at hardware dealers, or

SYRACUSE CORNER BLOCK FACTORY, SYRACUSE, NEW YORK

RELATIVE TO THE COCOMO CHISEL.

In any line of manufacture the competitors at the bottom are always numerous. As the quality ladder is climbed, the competition gets less and less. The P. H. Learner Company of Kokomo, Ind., claim that they have very little competition in the matter of high grade chisels. It is an axiom that "No product can be better than the responsible head of the manufacturing concern." No one who has ever come in contact with Mr. P. H. Learner can doubt his ability to produce a chisel of merit. Coming from good thorough-going German stock, with a natural aptitude for the handling of steel, and having given a persistent study and application to the securing of the best results, he is equipped in a peculiarly efficient way for obtaining results in this line of endeavor. In conversation with Mr. Learner we learn that he emphasizes the excellence of their chisel from the tip to the edge. They claim that they spare no expense ni the matter of securing the best crucible steel of special analysis, most experienced workmen and most approved processes. They emphasize the fact of the proper temper, neither too hard nor too soft, and the special shape of the blade. They are proud of their pattern of handle, which is shaped so as to give the maximum amount of comfort to the user. They also claim that the pattern and special grinding given to their beveled chisels, gives a lightness in the hands of the mechanic without affecting the strength of the chisel. Mr. Learner states that he can make a chisel for half the price that would look the same. He claims that it is what one can't see in his chisel that makes it so good.

An excursion through the Learner plant is of considerable interest. On its journey to a Cocomo chisel the bar steel is first taken to the shears and clipped in lengths of 2 feet each. These pieces are then placed in a forge and heated. The one end is then formed so as to receive the socket, if it is to be a socket chisel, or shaped into a tang if for a tang chisel. The socket is made of seamless steel tubing formed in a cone shape so as to telescope over the especially shaped neck of the steel bar. This embryo chisel is then returned to the furnace, heated to a welding temperature and is thoroughly welded together, after which the shear is again used, leaving a sufficient amount of steel which with the socket will make a tool of the proper length when it is turned out. A careful inspection is then made in regard to the welding.

In department 2 the tool is taken through another set of dies which forms the piece of steel into the proper shape and length. This process is technically known as plating. The smoothing operation is given by the socket being passed through another set of dies after it is heated. At this point the tool is brought to another shearer and clipped to the exact length. This is followed by straightening and a careful inspection. The chisel is then heated to the proper temperature and hardened in oil and after this given a lead bath. By means of a pyrometer this lead bath is kept at the proper degree of temperature so as to give the steel the proper temper. The pyrometer is infallible, so that it is impossible for the temper to be either too hard or too soft. At this stage every chisel is thoroughly and fully tested and then inspected with the greatest of care.

In department 3 the chisels are ground by experienced men on fine grain Huron grindstones. From there they travel to the edging machines and are properly edged so as to be sure and have every one of the proper width. They then pass back to another set of grindstones and have the cutting bevel put on them. Before being allowed to pass through the special beveling process they are again inspected and tested.

In department No. 4 the socket or tang is ground, when after another inspection they are passed into the polishing room where the polisher passes them over four grades of emery wheels. They are then returned to the grinding room where they are sharpened and where another test and most rigid inspection is given.

In department 5 they go into the hands of the polisher, where they are finished by being passed over three finer wheels.

On arriving in the stock room they are given their final examination. If the chisel passes this inspection it is oiled with pure olive oil, handled and then given its name, as an emblem of high degree, after which it is carefully polished with a soft woolen cloth and air slacked lime. After being polished the steel is never touched by the hand. It is packed in anti-rust paper and boxed for shipment.

COAL CHUTES.

Wherever it is necessary to put vegetables or fuel in a cellar, there is the need of an up-to-date chute to get them in.

The purpose of the chute is not only to get the materials in, but to do it without damage to the materials, the chute, or the surrounding property. Where there is no chute, broken glass, damaged frames and wasted materials are sure to result. Frequently the window, through which material is taken into the cellar, is left open or unlocked over night, an open invitation to the thief or other undesirables to come in. The damages to the sash frame and building will soon amount to the cost of a first class chute, while the annoyance attending the old style methods should settle the question at once in favor of an up-to-date chute.

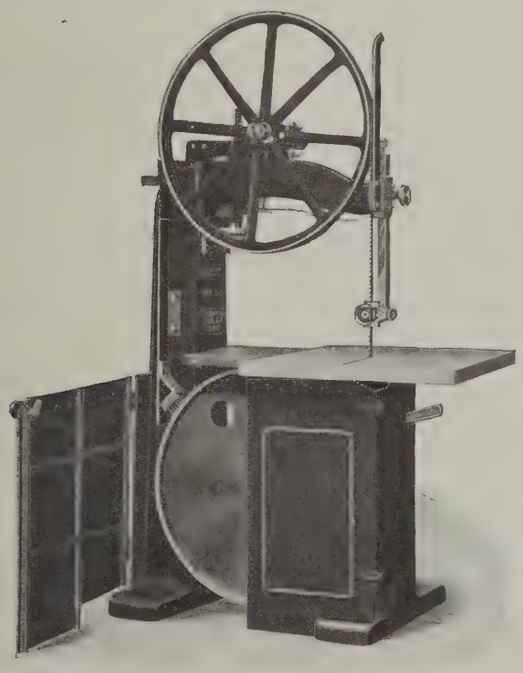
The Roenius Chutes, as manufactured by the Grand Rapids Foundry Co., Grand Rapids, Wisconsin, are made in three styles and 7 sizes. Some prefer a square chute, while others want a round one. Others want a little light through the cover. The manufacturers claim that in the six years they have been in business they have shipped chutes to every state in the Union and that their thousands of customers are all satisfied with them. It will be well for every prospective builder to have their circular, which gives far more information than can be crowded into these few lines.

PASTE THIS DOME ON LETTERS THAT YOU WRITE ADVERTISERS. IT WILL HELP.

STEEL SCAFFOLD BRACKETS.

In the erection of a building there is a great quantity of material and work furnished which does not appear in the finished work. There are runways over the soft ground, forms, cribbing and centering for the concrete, temporary closures for the windows, etc. Not the least is spent on scaffolding merely to hold the men and material in place until their work is done. With some contractors no effort is made to economize on this point, the safety of the men being the first consideration. With others, an attempt is made to save the poles, braces, etc., of which the scaffold is composed, but they do not always come apart without splitting, causing considerable loss of material. Others use built up wood brackets, heavy and cumbersome, occupying valuable space whether in use or in storage.

The American Steel Scaffold Company, 501 Woodward avenue, Detroit, Mich., has recently placed on the market a folding scaffold bracket, designed to take the place of the temporary constructions heretofore relied upon. Being made throughout of steel and designed to carry a load of 1,500 lbs., far in excess of any which is apt to come on it, it seems reasonable to believe the statements of the manufacturers that their use will save the cost of many brackets on each job. As they are easily folded when not in use and occupy a very small space, there is no occasion for leaving them around when not in use.



A scaffold of this description has many uses and advantages in all of them. Only one small hole through the sheathing is required, and whether the sides are shingled or whether branded, the scaffold can remain until the sides and cornice are finished.

Contractors who have used this scaffold enthusiastically endorse it. Contractors and carpenters should have the circular describing these scaffolds in detail. The American Steel Scaffold Company is always glad to advise prospective purchasers regarding teh use of these scaffolds or their adaptability to any certain class of work.

THE BAND SAW IN THE SHOP

The most important machine in any wood shop, especially the Carpenter, Contractor or Builder. It follows, therefore, that the Band Saw purchased for use in such a shop must be chosen for its ability to stand up to hard work and of all kinds day in and day out. Nothing is more annoying than to have a machine which will break a blade or go to pieces right in the middle of a rush job.

Undoubtedly, the best all around Band Saw now made is the Fay & Egan Co., No. 50. W. S. Milne, the large chair manufacturer of Cleveland, Tenn., says that after seeing one of these machines in operation in another factory he immediately decided to purchase a Fay & Egan No. 50 the next time he needed a machine of this type. He got such excellent results from the first that he has since purchased eight more, now having nine of these tools running in his factory.

The illustration herewith shows one of the latest improvements to this machine, the iron doors over the lower wheels, eliminating any chance of the operator getting caught in the lower wheel.

The success of this machine is attributable primarily to Fay & Egan's Patented Knife Edge Straining Device. This device is so sensitive that it will compensate for even the smallest chip sticking to the blade or rim of the wheel. Broken blades are practically unknown where this strain is used, the sum saved in this respect alone amounting to quite a little in a short while.

This Patented Strain in connection with the Solid Lower Wheel permits the use of a thinner blade at a higher speed than was ever known before, increasing the quality as well as the quantity of the work.

The square form of column, cast in one piece gives great rigidity to all working parts. For pattern work, the table is arranged to angle to 45 degrees with micrometer adjustment.

Further information regarding this Band Saw may be obtained by addressing the manufacturers, J. A. Fay & Egan Co., 327-347 W. Front St., Cincinnati, Ohio.

Learn to Fill BIGGER SHOES!

HOW YOU CAN DO IT

You can *master every detail* of your line of work, *every branch* of building construction, *every angle* of architecture and carpentry—can do it in your spare moments and at almost no expense at all. You can have the knowledge and experience of over *four score experts* at your command, ready for instant use whenever you want it—can fit yourself to *fill any first class position above you that you desire*—simply by allowing us to place in your hands this great ten volume set *without your sending us one cent in advance.*

This Cyclopedia of Architecture, Carpentry and Building

is the most exhaustive, comprehensive and *practical* work on the building trades that has ever been published. It covers *every detail* of building construction from common carpenter work to reinforced concrete and steel; from masonry to heating and ventilation; from specifications and estimates to building laws and superintendence. It covers all the *practical* things that you *want* to know, all the things that you've *got* to know if you're going to be a success. It contains over 3,000 drawings, full page plates, diagrams, etc., has 4,670 pages, is bound in handsome half morocco and printed on special paper in large clear type—10 massive volumes—titles engraved in 23 karat gold. No *carpenter, contractor* or *building owner can afford to be without it a single day.*

Learn the Vitally Important, Practical Facts About

PLUMBING AND STEAM GOODS.

The 1911 catalogue of B. Y. Karol, 768-772 West Harrison street, Chicago, shows a complete line of fittings for the purposes mentioned. With an experience of twenty years, Mr. Karol has seen a remarkably growth in the plumbing goods industry and has had much to do with raising it to the high standard it now holds. A large stock of goods enables him to ship promptly and his long experience would indicate that an order would be promptly and properly filled.

Mr. Karol, while supplying all the standard plumbing goods, supplies and accessories, also sends out complete outfits of various combinations of fixtures. Many times a considerable saving can be made by uniting several fixtures in a set, besides giving a more harmonious appearance to the house. One of the many combinations which he has on hand is shown in the cut herewith, and intending purchasers should write him when in the market for goods in his line.

CEMENT BRICK MACHINERY.

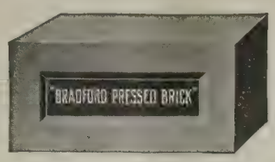
In the search for materials calculated to insure permanence, fireproof qualities and good appearance, cement is a most important factor. The durability of cement products in almost any of its forms is well known, and its fireproof qualities are a matter of record. When the artistic design and appearance are considered, however, there is a great variety of expression which concrete and cement are capable of expressing. Possibly, in no material is there a greater range. We get the massive effect of the monolithic structure, the rough appearance from the rough cast on metal lath, cut stone effects at a fractional cost from block construction, etc. For certain conditions each construction may be adapted, but for the best appearance under nearly all conditions, nothing equals the standard size cement brick. The clay brick has held its size for so many centuries with comparatively little variation in size that it truly represents the ideal form of architectural expression. The advantage of cement bricks over clay bricks are numerous and apparent. There is a uniformity in size, color and texture which is hard to obtain in clay. For the same quality, the cement brick has the advantage in cost. For moulded courses and decorations, the cost of clay brick is practically prohibitive, while the cost in cement brick is no greater than common brick.

In the manufacture of cement brick, however, great care must be taken to obtain the best results. Many of the machines now on the market are defective mechanically and a first-class product is impossible on them. The Raber & Lang Manufacturing Company, of Kendallville, Ind., make a machine which they claim overcomes all the objections of the most critical. They claim the machine has a capacity of 12,000 brick per day when operated by one man with two assistants. This reduces the cost far below the cost of common brick, and there is no delay waiting for them. A copy of their circular should be in the hands of every cement contractor, that he may realize the opportunities in the business. A postal brings it.

FOX UNIVERSAL TRIMMERS.

Pattern Making, Cabinet Work, Joinery, Carpentry, Picture Framing, and many other trades require accuracy, and at the same time speed. Where a perfectly plane surface on either hard or soft wood, at any given angle from any other face is required, a machine of the trimmer class is practically indispensible.

The Fox Universal Trimmer was designed by a pattern-maker, having the exacting requirements of that trade in mind. The improvements made from time to time to the original design, as suggested by its use in other trades, makes the name "Universal" particularly significant. The trimmer is built upon the principle of a shearing cut, and consists of a bench somewhat similar to a mitre box, on which the material may be fixed at any angle. A knife shearing against the point of a gauge, which is made to swing in the arc of a circle, cuts or "trims" the exposed surface to a perfectly plane surface.



The manufacturers of the Fox Universal Trimmer call attention to two particular features of construction.

First—Pivoting the edge of the gauge in such a manner that the shearing edge of the gauge always remains in the same position in relation to the cutting edge of the knife, no matter at what angle the gauge may be set.

"You Get the Job"

That's what the trained man, the expert in his line, hears today from the man that hires.

Training lands the job—training that means high-grade work and a short cut to results. And training wins quick advancement to still better jobs.

The day of the "Jack-of-all-trades" is passed. This is the time of the specialist. No concern can afford to place a high-grade equipment in the hands of low-grade men. Competition forces employers to meet skill with skill.

The business of the International Correspondence Schools is to supply training; to give job-getting and job-bettering ability; to raise salaries.

Every month upward of 400 I. C. S. students write to Scranton to tell of positions secured or bettered—of earnings increased and prospects brightened—through study of I. C. S. Courses. Last month the number was 416. The letters come from every section and from all sorts and conditions of men.

All got the education—the training that enabled them to get work they liked and advance in it. They furnished the ambition and perseverance. The I. C. S. furnished the training.

If you wish to make sure of the job you want—there is an I. C. S. way for you. To find out all about it, mark and mail the coupon. Doing so will commit you to nothing, place you under no obligation, and may prove to be the turning point in your career. Dont wait.

Mail the Coupon Now!

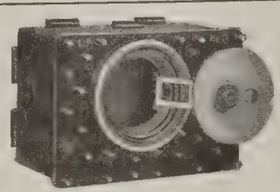
Second—We apply power to the knife carriage in such a manner that the wear upon the ways is distributed uniformly along the whole surface.

The machines are built in three styles; the style "A" machine being a bench type machine; the style "E" machine being a machine with legs which is intended for pattern shop use, and the style "F" machine, which is to take in the largest pattern shop work, the machine being mounted on a bed having castors, so that it may readily be moved from one point to another. From this it will be seen that the use of a trimmer is not confined to the large shop. The smaller sizes are made for convenient working on a bench, and are easily taken from job to job if the work requires it, and yet they are rigid enough to handle any work coming within their range with perfect accuracy. While no shop can afford to be without at least one of the larger size trimmers, each pattern maker or cabinet maker should have an individual trimmer for his exclusive use.

To acquaint everyone with the scope of work capable with their trimmers, the Fox Machine Company, 26 North Front Street, Grand Rapids, Mich., are sending out a very complete catalogue. An unusual feature in the catalogue is the listing in two tabulated specifications in English measure and metric, the weights, sizes, etc., of the various style trimmers. The list shows a 32-pound trimmer making a cut 4 inches high and 8 inches long, and other styles up to a 700-pound machine making a cut 8 inches high and 24½ inches long. A prospective purchaser should have little difficulty in selecting the machine suited to his requirement, but if he should have special work to do, the Fox Machine Company will be pleased to assist him in any way possible.

HOW SHE GOT IT.

A little girl was sent by her mother to the grocery store with a jug for a quart of vinegar.



"But, mamma," said the little one, "I can't say that word!"

"But you must try," said the mother, "for I must have vinegar, and there's no one else to send."

So the little girl went with the jug, and, as she reached the counter of the store she pulled the cork out of the jug with a pop and said to the astonished clerk:

"There! Smell of that and give me a quart!"—Exchange.

LOW GRADE LUMBER AND THE BUILDER

A NEW note or a new tenor of argument has entered into the deliberations of the various retail lumber dealers' associations this year, probably inspired partly by sawmill men, as a result of which there will probably be more low grade lumber than heretofore offered the building trades.

Low grade lumber is getting to be quite a burden to sawmill men, because of the desire to clean up their trees closer, makes lots of timber lower in quality, so that the precentage of low grade runs higher than it did. Also the spirit of thrift and economy creates a natural desire to utilize material that heretofore was thrown in the waste pile.

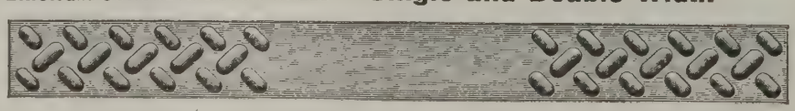
Just how this may affect the builder remains to be seen. From certain angles it looks like a benefit may derive from it that will be divided between the builder, retail lumber dealer, and the sawmill man. Looked at from other angles, it appears as if there is a chance for the builder to have more trouble with his lumber than ever before, because of the injection of low grade stuff into it.

Quite a lot depends on both the intelligence and honesty with which the matter is handled. If the retail dealer figures on handling a lower grade lumber and foists it on the building trades as representing the same old grades, it means trouble and annoyance. The claim is made that some of this has already been done, that some of the dealers use a good grade of No. 3 boards and pass them off as No. 2, and a good grade of No. 2 common framing and pass it off as No. 1.

Things of this kind are to be deplored. If there is a good grade of No. 2 framing that will do in lieu of No. 1 it should be sold for what it is and the price made so that the builder and the lumberman may divide the profit. The same is true of boards.

If the thing is taken up in an honest, co-operative spirit, however, both the builder and lumber dealer may profit by the use of a greater percentage of low grade lumber. In the present day there is a chance to use quite a lot more low grade both in framing and in sheathing if attention is given to it. There are various ways its use may be encouraged. There are lots of short lengths in framing that No. 2 common will do as well as No. 1, and there are occasions where larger dimensions in No. 2 would be preferable to small ones in No. 1. Then in boards for false work to do concreting there is no need for anything but low grade. The complaint is often made that too much lumber is wasted and destroyed in this kind of work. All that is wanted is something that will hold the concrete while setting and here lots of low grade might be used. Also, for storm sheathing and in connection with the use of thin hardwood floors there is a chance to work in quite a lot of low grade by proper cutting and refining. Then in planing mill work there is a chance to trim low grade and refine it for what clear stock is present in it, and there are many opportunities for both the lumbermen and the builders to utilize some of this low grade to their mutual advantage provided they go about it in a co-operative spirit.

No one knows just what spirit the matter will be taken up with, but since the subject is opened up and it is liable to be a matter of experiment it behooves every builder to be on the look-out and be in touch with his lumber dealer so as to know what is what and be prepared to protect himself, or either in co-operation with his lumber dealer, as occasion may require.



BATH ROOM COMFORT.

The introduction of the Never-split Seat marks a new era in bath room appointments.

The ordinary closet seat depends upon glue alone to hold it together at the joints. Glue loses its adhesive power when exposed to dampness or heat and hence the seat in the majority of homes soon splits and becomes not only uncomfortable but unsanitary. This seat made by Never-Split Company of Evansville, Ind., has a strong steel bolt in every joint in addition to the tongue and groove. In shape and finish, perfection is an adjective that truly describes this modern improvement.

Amatite ROOFING

Why the Buyer of Amatite Never Complains

WHEN a man buys ordinary ready roofing he usually neglects to paint it and after three or four years he comes back to the dealer with a protest. It is human nature to neglect painting roofs.

When a man buys Amatite Roofing he lays it on his building and in three or four years it is still as good as new and does not need any paint. He forgets he has such a roof but no harm is done by that.

There is nothing to neglect in the case of Amatite. Amatite has a peculiar surface—a sort of plastic concrete made of pitch and mineral matter.

This surface is plastic enough so that the material can be rolled up into handy rolls in the usual manner and handled just like any other ready roofing. When unrolled on the roof and nailed down it presents to the weather a continuous surface of mineral matter and pitch. On this surface wind, rain, storm, heat and cold have little effect. Year after year it looks up to the sky undisturbed and unaffected. It costs nothing to maintain and relieves the owner from all responsibility.

Dealers can improve their business by selling Amatite and buyers make a good bargain when they buy it. The price of Amatite is less than that of most painted roofings of less weight and durability.

Sample free on request. Address our nearest office.

Diehl's Separable and Reversible Hinge No. 20

This hinge is designed for storm and screen doors. The door may be swung at right angles and lifted from its bearings without removing the screws, as the shank slides through the small slot in the upper ear so that it makes it very easy to change from storm to screen doors and from screen to storm doors without removing the hinges. Hinge No. 20 is made of open hearth wrought steel, 14 gauge, and finished in black baked japan or oxidized copper.

A Sample Set of Hinges will be sent upon receipt of 25 cents in stamps.

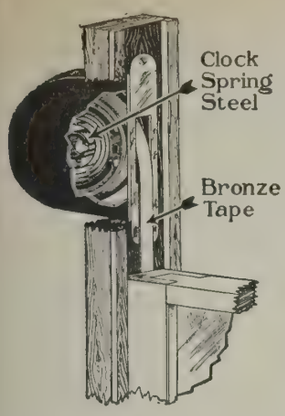
GREYHOUND HAND SAWS

SPEED & EASE
TRADE MARK.

The more you know about hand saws the more you can appreciate "GREYHOUND" hand-made hand saws, with their easy-running and rapid cutting qualities and wonderful durability. This saw will be imitated by others—but not equalled.

They are made from Bishop's Refined "GREYHOUND" Steel—a material which leads everything yet produced for use in hand saws. The purity of the steel, the toughness, the even and accurate temper, gives a saw that is the most suitable for particular work, and the most practical for ALL work where a hand saw is used. Made in both straight and skewback, also narrow patterns. Specify which you desire. Remember our warranty accompanies each saw. And the warranty means that if 30 days' trial does not convince you that the "GREYHOUND" saw is the **best** for your use, you get your money back.



Order one today and let us take all the risk. If you want literature first, write us.

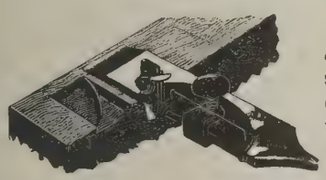
Miller's Two Minute Lever Lock Mortiser

Chisels the opening for Locks and is the greatest time and labor saver



One builder wrote us last month: "You may expect an order for 3 machines as the carpenters are going crazy about my machine. The more I use it, the better I like it."

THINK THIS OVER, MR. CONTRACTOR AND BUILDER

Our patent double edge, side cutting chisel can cut more wood, four times more rapidly and 100% less exertion than any boring bit. Mortise to be of the same size.

MILLER'S TWO MINUTE LOCK MORTISERS

are sent on trial to any reliable contracter and builder. Write for circulars and order now for spring work.

We also make a Butt Mortiser and Rule Gauge which cuts out the seats for butt hinges in soft or hard doors, jambs and similar work—which we will send you postpaid for ***75 cents.***

A. W. MILLER MFG. CO.

Nevada Building, CINCINNATI, OHIO Western Office, RIVERSIDE, CAL.

DON'T PUT SASH WEIGHTS IN YOUR WINDOWS—THEY ARE OUT OF DATE

THE "AUTOMATIC" SASH HOLDER

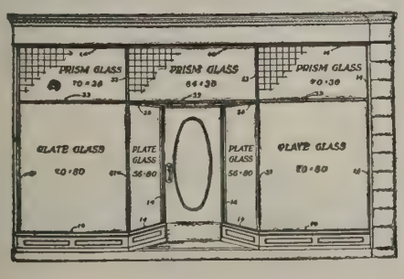
is better and cheaper, more convenient, less perplexing, easier to put in, more reliable, more durable, more satisfactory.

The "Automatic" Sash Holder is the new modern, up-to-date device that dispenses with cumbrous sash weights, kinking cords or ribbons, useless weight pockets, misfit pulleys and reluctant balances, and saves all the time, labor and expense of fitting them in place.

Architects are specifying them, Contractors and Builders are buying them. Sash and Planing Mills are providing for them, Carpenters are putting them into old and new buildings.

Prevent rattling and permit the window to be moved up and down with ease. Hold it safely at any point desired.

Sample sent on request



Sold by hardware dealers or direct from us. Correspondence solicited. Representatives and side line travelers wanted all over the world.

AUTOMATIC SASH HOLDER CO.

279 Broadway, New York City.

Style——Strength——Safety

For that new Store Front specify the Petz Bar, and see that you get it. Not only beautiful and strong, but you can install it without fear of breaking the glass, which happens so often with some bars.

The Petz System is highly recommended by leading architects and insurance experts. It gives perfect ventilation and is quickly and easily installed.

Why not write today for our booklet, "Modern Store Front Construction," illustrating and describing Petz Bars with opinions of prominent users? Address

You are Looking for Information on Concrete

Every Architect, Contractor and Builder should have a copy of

Concrete and Reinforced Concrete Construction

By HOMER A. REID

200 working drawings of bridges, bridge piers and culverts; 60 working drawings of sewers, water mains and reservoirs; 30 working drawings each of retaining walls and dams; 200 working drawings of buildings and foundations, including shops, roundhouses, etc. Every structure illustrated is described, the method of construction is explained and where possible the cost is given. There are chapters telling **how to compute girders, arches, columns, tanks, bins, walls, conduits and chapters on proportioning, mixing and laying concrete,** on **doing concrete work in freezing weather,** on **facing and finishing concrete,** on **waterproofing concrete,** on the **physical properties of concrete,** on **cement testing** and on **concrete block manufacture and construction.**

This book contains more text pages, more drawings and **more tables of test data on concrete and reinforced concrete construction than any other book in the world. It has more new matter**—material never previously published. This work is a combination of several books in one; **it is complete, up-to-date and original. No other book on concrete contains one-tenth as much of the very latest data on tests, theory, and practice.** The cost to publish this book has been more than double the original estimate, but the price will for the present remain at $5 net postpaid. Order **now.**

New Books for Building Mechanics

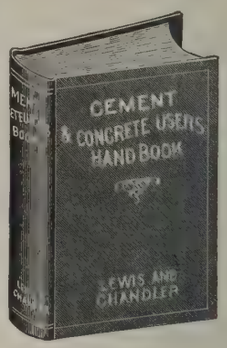
MODERN PLUMBING ILLUSTRATED. By R. M. Starbuck.

This book represents the highest standard of plumbing work. It has been adopted and used as a reference book by the United States Government, in its sanitary work in Cuba, Porto Rico and the Philippines, and by the principal Boards of Health of the United States and Canada.
It gives connections, sizes and working data for all fixtures and groups of fixtures. It is helpful in demonstrating and in figuring work. It gives the mechanic quick and easy access to the best modern plumbing practice. Suggestions for estimating plumbing construction are contained in its pages. This book represents, in a word, the latest and best up-to-date practice, and should be in the hands of every architect, sanitary engineer and plumber who wishes to keep himself up to the minute on this important feature of construction. 400 octavo pages, fully illustrated by 55 full page engravings. Price.....**$4.00**

STANDARD PRACTICAL PLUMBING. By R. M. Starbuck.

A complete practical treatise of 450 pages covering the subject of Modern Plumbing in all its Branches, a large amount of space being devoted to a very complete and practical treatment of the subject of Hot Water Supply and Circulation and Range Boiler Work. Its thirty chapters include about every phase of the subject one can think of, making it an indispensable work. Fully illustrated by 347 engravings. Price.....**$3.00**

PRACTICAL STEAM, HOT-WATER HEATING AND VENTILATION. By A. G. King.



This book is the standard and latest work published on the subject and has been prepared for the use of all engaged in the business of steam, hot water heating, and ventilation. It is an original and exhaustive work. Tells how to get heating contracts, how to install heating and ventilating apparatus, the best business methods to be used, with "Tricks of the Trade" for shop use. Rules and data for estimating radiation and cost and such tables and information as make it an indispensable work for everyone interested in steam, hot water heating and ventilation. It describes all the principal systems of steam, hot water, vacuum, vapor, and vacuum-vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation and the fan or blower system of heating and ventilation. 367 pages. 300 detailed engravings. Price.....**$3.00**

CONCRETE CHIMNEYS, SLATE AND ROOF TILES. By A. A. Houghton

The manufacture of all types of concrete slate and roof tile is fully treated. Valuable data on all forms of reinforced concrete roofs are contained within its pages. The construction of concrete chimneys by block or monolithic systems of is fully illustrated and described. A number of ornamental designs of chimney construction with molds are shown in this valuable treatise.....**50 Cents**

POPULAR HANDBOOK FOR CEMENT and CONCRETE USERS. By Myron H. Lewis

This is a concise treatise of the principles and methods employed in the manufacture and use of cement in all classes of modern works. The author has brought together in this work, all the salient matter of interest to the user of concrete and its many diversified products. The matter is presented in logical and systematic order, clearly written, fully illustrated and and free from involved mathematics. Everything of value to the concrete user is given, including kinds of cement employed in construction, concrete architecture, inspection and testing, waterproofing, coloring and painting, rules, tables, working and cost data. Price.....**$2.50**

ORNAMENTAL CONCRETE WITHOUT MOLDS. By A. A. Houghton.

The process for making ornamental concrete without molds, has long been held as a secret and now, for the first time, this process is given to the public. The book reveals the secret and is the only book published which explains a simple, practical method whereby the concrete worker is enabled by employing wood and metal templates of different designs, to mold or model in concrete any Cornice, Archivolt, Column, Pedestal, Base Cap, Urn or Pier in a monolithic form—right upon the job. These may be molded in units or blocks, and then built up to suit the specifications demanded. This work is fully illustrated with detailed engravings Price.....**$2.00**

CONCRETE FROM SAND MOLDS. By A. A. Houghton.

A practical work treating on a process, which has heretofore been held as a trade secret by the few who possessed it, and which will successfully mold every and any class of ornamental concrete work. The process of molding concrete with sand molds is of the utmost practical value, possessing the manifold advantages of a low cost of molds, the ease and rapidity of operation, perfect details to all ornamental designs, density and increased strength of the concrete, perfect curing of the work without attention and the easy removal of the molds, regardless of any undercutting the design may have. 192 pages. Fully illustrated. Price.....**$2.00**

CONCRETE WALL FORMS. By A. A. Houghton.

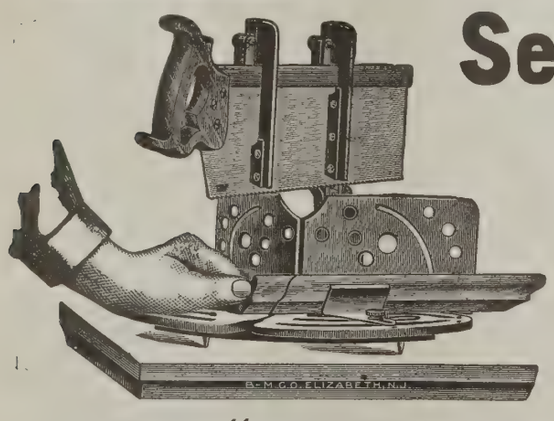
A new automatic wall clamp is illustrated with working drawings. Other types of wall forms, clamps, separators, etc., are also illustrated and explained.....**50 Cents**

CONCRETE FLOORS AND SIDEWALKS. By A. A. Houghton.

The molds for molding squares, hexagonal and many other styles of mosaic floor and sidewalk blocks, are fully illustrated and explained.....**50 Cents**

CONCRETE SILOS. By A. A Houghton.

Complete working drawings and specifications are given for several styles of concrete silos, with illustrations for molds for monolithic and block silos. The tables, data and information presented in this book are of the utmost value in planning and constructing all forms of concrete silos.....**50 Cents**



MOLDING AND CURING ORNAMENTAL CONCRETE. By A. A. Houghton.

The proper proportions of cement and aggregates for various finishes, also the methods of thoroughly mixing and placing in the molds, are fully treated. An exhaustive treatise on this subject that every concrete worker will find of daily use and value.....**50 Cents**

Any of these books sent prepaid on receipt of the price. Address **NATIONAL BUILDER, Pontiac Building, CHICAGO, ILLINOIS**

IT'S A PLEASURE TO USE FINE SAWS

Saws That Hang Just Right — That Run Easiest — That Cut Fastest
That Saw to the Mark — That Take a Sharp Cutting Edge and Hold It

We have made a life-long study of saws. Long before many of you were born, E. C. ATKINS & COMPANY were already making saws. We know better than anybody else what the high-class mechanic wants in a saw, and we know how to make saws that give satisfaction.

Is This the Kind?

Do you want a saw that sharpens easily, that holds its tension, that will receive a very sharp cutting point and hold it? Do you want a saw that cuts fast and easy and true and that hangs just right, so that it will run with the least exertion?

Then you should by all means use an ATKINS SILVER STEEL SAW because they will do these things for you.

Guarantee

These are rather broad statements to make, but we back them up by the broadest possible guarantee. ATKINS SILVER STEEL SAWS are not only guaranteed to be perfect in material and construction, but we guarantee them to give perfect satisfaction. Listen to this: If your ATKINS SILVER STEEL SAW, for **any reason,** does not cut faster, run easier and hold its edge longer than any saw you ever used—take it back to your dealer and get **your money back** or a new saw. No argument, no proof is necessary; don't hesitate—just take it back and get your money, that's all. If your dealer even hesitates, show him this advertisement and, if necessary, let us know. We'll see that you get satisfaction. Can we make it stronger—can we give you better protection?

The reason we can do these things is because we know all about our saws. We make them ourselves.

SILVER STEEL

SILVER STEEL is the finest material that has ever been used in saw blades. It is made of virgin ore and contains the very highest ingredients and is manufactured under an exclusive formula. It is as fine as the steel that is used in most high grade razors, and when we tell you that it will receive a sharper cutting edge and hold it longer than any other steel, we know what we are talking about.

Taper Grinding

ATKINS SAWS are the only saws which are ground on an actual taper from the tooth edge **throughout** the entire blade toward the point on the back. They are different from the thin back saw which is simply ground off along the back, while ATKINS SILVER STEEL SAWS are ground on an actual taper throughout the entire blade.

The Handle

Many of our SILVER STEEL SAWS are made with the old style straight across handle, but most high-class mechanics prefer the Perfection Handle because it is scientifically constructed and saves the wrist and saw arm.

Go to your dealer and ask him to show you a genuine ATKINS SILVER STEEL SAW and note these things for yourself. If your dealer does not carry them in stock, he will order for you from his wholesale house. Insist on an ATKINS SILVER STEEL and see that our name is on the blade.

OUR FREE OFFER—If you will send us ten cents in currency or stamps we will forward you, free of charge, a high grade carpenters' nail apron, also our Saw Sense book, illustrating and describing our most popular saws, together with a carpenter's time book and wage scale, also a great deal of useful information in regard to High Grade Saws. DISSTON

INSULATE SCREW DRIVER

This tool is designed expressly for Electricians' use.
The blade of crucible steel, hardened and tempered, is embedded in a handle of hard rubber of a texture that eliminates brittleness. It *will not* work loose.
The rubber handle is milled grip with projecting rings which prevent the hands from slipping down onto the blade.
The hard rubber handle acts as insulation.
The Disston Insulate Screw Driver is something new.
Most practical electricians' screw driver ever made.

BISHOPRIC WALL BOARD AND SHEATHING

ANY WEATHER is "Good Building Weather" when you use Bishopric Wall Board as a substitute for lath and plaster. It is cheaper and better and does away with all delays in building. It is nailed to studding dry, ready for immediate application of paper, paint, burlap, or any other kind of decoration.

FOR WALLS AND CEILINGS

Bishopric Wall Board Easily Applied

This substitute for lath and plaster is made of kiln-dried, dressed lath, imbedded in hot Asphalt Mastic, surfaced with sized cardboard and cut at the factory into 4x4 ft. sheets, which are easily and quickly nailed to studding, ready for immediate application of wall paper, paint, burlap, or other decoration.

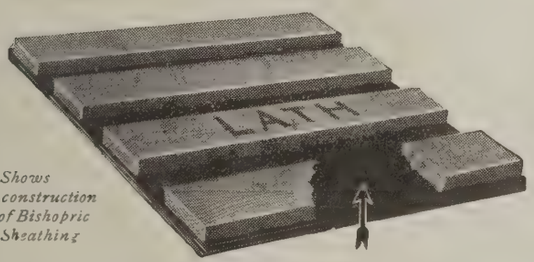
It is applied dry, is guaranteed not to swell, shrink, warp, crack, flake or blister; is clean, sanitary, and odorless; is proof against moisture, cold, heat, and vermin; saves fuel in winter and keeps out summer heat; also deadens sound.

It is suitable for dwellings, factories, new partitions in old buildings, finishing attics, porches, laundries, cellar ceilings, garages, etc.

Applied Dry Winter or Summer

Shows Construction of Bishopric Wall Board.

PRICE WALL BOARD AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6.40 per crate, or $2.50 per 100 square feet, f. o. b. New Orleans, La., Cincinnati, or Alma, Mich. We ship from nearest point.



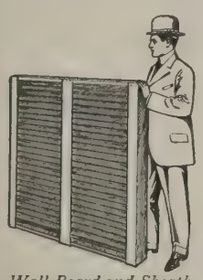
Cheaper Than Lumber. Saves 75% on Labor. Does away with Building Paper.

BISHOPRIC SHEATHING

Ideal Material for Cement Buildings or Stucco Exteriors. Proof against Dampness.

Bishopric Sheathing is made of same materials as Wall Board, but finish is not necessarily so fine, therefore costs less. It is of uniform thickness, insuring a perfectly even surface when applied.

Bishopric Sheathing is nailed to studs, with lath and asphalt side exposed. Over laths, weather boards are nailed or cement applied.



Shows construction of Bishopric Sheathing

Arrow points to Asphalt Mastic into which laths are imbedded.

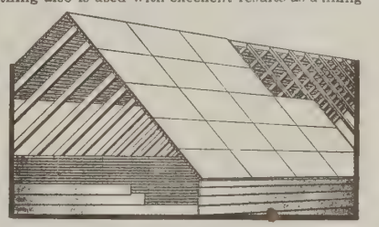
Bishopric Sheathing makes a more solid and substantial wall than lumber. There are no gaping joints; no widening cracks due to shrinkage; no knot holes.

The Asphalt Mastic in Bishopric Sheathing is a non-conductor, moisture cannot penetrate it. It is proof against vermin. The pests cannot bore through the tough, gummy Asphalt Mastic. In applying weather-boards over the laths, dead air space is left between the laths forming splendid insulation. Does away with the expense of building paper and cost of its application.

One Wagon load of Bishopric Sheathing covers an area from six to ten times as great as one load of lumber—a tremendous saving in hauling. Five thousand feet can be hauled in an ordinary wagon.

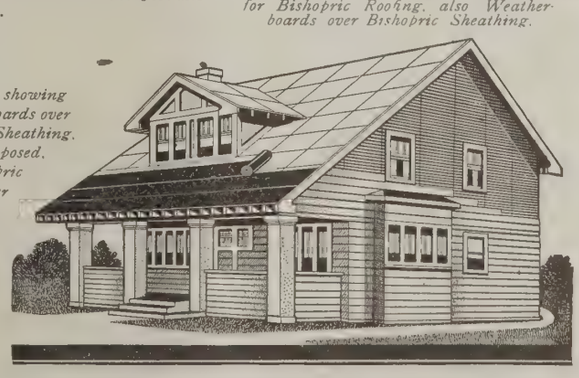
Wall Board and Sheathing are shipped in crates

The cost of applying Bishopric Sheathing is but $2.50 per 1000 feet—A SAVING OF ABOUT 75 PER CENT. Furthermore, 1,000 square feet of wood sheathing covers but 750 feet of surface, 20% less being due to tongue and groove. In Bishopric Sheathing 1,000 square feet covers 1,000 square feet of space



In applying ordinary lumber, heavier scaffolding, more tools and greater scaffold floor-space are required In applying Bishopric Sheathing, one man drives a few nails in each sheet; a common laborer or boy can finish the nailing.

Bishopric Sheathing insures comfort during the construction of the building. As soon as the building is closed in with Bishopric Sheathing, the men may work in comfort on the inside during bad weather, finishing the outside on suitable days. This insures continuous work, without loss of time, enabling the contractor to hold his men and complete the work in the least possible time



Bishopric Sheathing is used with equally splendid results under flooring and as a substitute for roofing boards. Used under floors, it serves as a sound deadener and keeps out dampness; used under the shingles, it keeps out summer heat.

ITS MANY USES—Bishopric Sheathing also is used with excellent results as a lining for dairy barns, ranch houses, poultry houses, driving stables or any out-door building where protection from the elements, Summer or Winter is desired.

Bishopric Sheathing is the ideal material for cement exterior or stucco work. Cement firmly adheres to the laths and Asphalt Mastic and makes a solid, smooth exterior. For factory or residence this form of cement or stucco construction is the cheapest and best known.

Shows Bishopric Sheathing over rafters ready for Bishopric Roofing, also Weather-boards over Bishopric Sheathing.

Ideal home showing Weather-boards over Bishopric Sheathing, lath side exposed, also Bishopric Roofing over Bishopric Sheathing. (smooth side of sheathing exposed)

PRICE SHEATHING AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6, or $2.35 per square of 100 square feet, f. o. b. New Orleans, La., Cincinnati or Alma, Mich. We ship from nearest point.

Write for Descriptive Booklet and Samples of Bishopric Wall Board, Bishopric Sheathing and Bishopric Roofing—All will be sent free.

Utility Wall Board

Is Used on Walls and Ceilings of These Artistic Rooms

The first illustration shows how easily Utility Wall Board can be applied. The other two illustrations show how nicely wall paper can be applied on walls and ceilings lined with Utility Wall Board.

Does it not look good to you ?

Wouldn't you like to have us send you a sample of it—and tell you how economical it is—How easily it is applied—How artistically it can be decorated?

Our *beautiful illustrated booklet* tells the whole story—and shows pictures of artistic interiors. It is free for the asking, together with a sample of Utility Wall Board.

UTILITY WALL BOARD

is unlike any other Wall Board you have ever seen—It is made of exceedingly tough, durable fibre, thoroughly waterproofed—No moisture can penetrate it—It is applied directly to the studding, taking the place of both lath and plaster—Any carpenter can put it on—It will last as long as the house stands—You'll be amazed at the convenience of it—the economy of it—the beauty of it.

Mr. Contractor: This is your chance to make more money and finish your jobs quicker. UTILITY WALL BOARD is right in quality and price. It has come to stay and is rapidly taking the place of lath and plaster.

Every up-to-date contractor and builder should get samples of UTILITY WALL BOARD at once. There are hundreds of places it can be used with a profit to you and satisfaction to the owner.

Remember that all delays of the plasterer are a thing of the past for those who use this modern wall lining.

Don't fail to send for the sample and booklet at once—ask for our special proposition to contractors and builders

UTILITY WALL BOARD is Sold Through Dealers in Building Material Everywhere

THE HEPPES COMPANY

4502 Fillmore St., Chicago, Ill.

SEE THAT

Compo-Board

IN IN YOUR SPECIFICATIONS

It is the most satisfactory wall lining yet devised. It will last longer than lath and plaster.

Compo-Board is easily and cleaply put on, and the walls will look well as long as the building lasts. They will never be disfigured with ugly cracks or blemishes from moisture accumulating on the walls. Will not crumble, crack or fall off. Cannot be marred by jamming furniture into them. ¶ Compo-Board makes dry, warm, moisture-proof, fire-resisting walls, ceilings and partitions. The rooms will be free from draughts, warm in winter and cool in summer. ¶ Not only is Compo-Board a superior wall lining, but it has many uses around the house, in offices and factories. ¶ It is made of thoroughly seasoned, kiln dried strips of lumber well glued together. They are covered with a thick coat of cement on either side and an outside covering of thick paper.

You can buy it in strips four feet wide and one to 18 feet long, any length you want in even feet. **Send for BOOKLET and SAMPLE.**

It explains the many uses and advantages of Compo-Board and you can get an idea of what it is from the sample.

SAP GUM

The success of ***RED GUM*** in New York building operations—both large and small—has been most pronounced.

Any builder who wants to be up-to-date may find several hundred high class apartment buildings and residences in which ***RED GUM*** has been selected for the interior trim because of its beauty and value.

SAP GUM

(which comes from the same tree) is not yet so generally known perhaps because it lacks the superb grain and color of ***RED GUM*** and because it is usually used where it does not show. (***SAP GUM*** is the ONE BEST WOOD known for WHITE ENAMEL TRIM, for instance.)

Builders who don't yet know about ***SAP GUM*** will find it is thoroughly reliable when properly manufactured, and will find, furthermore, that ***SAP GUM*** has all the good qualities of many of the woods hitherto used merely through force of habit.

Get any of the following trim manufacturers

Genasco is the roofing of the age. Its foundation has stood for ages past.

It beats shingles. They warp, crack, split, and rot—more so now than ever before (lumber is getting scarcer, and shingle-quality is becoming poorer every year).

Beats tin, which rusts and needs painting regularly. And even with paint tin doesn't last like it used to—quality has deteriorated here, also.

Coal tar roofings have the same old faults they have always had—get soft and melt in the summer sun, and get brittle and crack in the cold, and leak.

Genasco

the Trinidad-Lake-Asphalt Roofing

is the one roofing that lasts. It is made of Nature's everlasting waterproofer. Trinidad Lake Asphalt has withstood the suns and storms of centuries; and in Genasco it gives this same lasting resistance to sun, rain, snow, wind, heat, cold—and even fire. The oily nature of this natural asphalt keeps Genasco alive and strong to defend itself; and this is why Genasco is lastingly waterproof.

The Kant-leak Kleet waterproofs the seams of Genasco without cement, and prevents nail-leaks besides. It gives the roof an attractive appearance.

Ask your dealer for Genasco mineral or smooth surface Roofings with Kant-leak Kleets packed in the roll. Guaranteed, of course. Write us for samples and the Good Roof Guide Book.

DO YOUR MILL WORK ON THE JOB WITH THE "AMERICAN" PORTABLE SAW BENCH

This shows the Gasoline Engine Driven Style.

We can also furnish the "American" with Motor Drive for any current.

How often you have wished that your job was near the mill, so you could do a large part of your work by machine, instead of by hand.

An "American" Portable Saw Bench on your work will put mill facilities right at hand; and the time and labor this will save you means money in your pocket.

In all probability, an "American" Bench will pay for itself on the first job; and its savings on subsequent jobs will swell your profits.

For the "American" Saw Bench is not a "one-job" tool. **It is built to the "American" standard, which means that it will prove a permanently profitable investment, year after year.**

An "American" Saw Bench is the greatest money-maker a contractor can own.

Ask us to send you a descriptive circular.

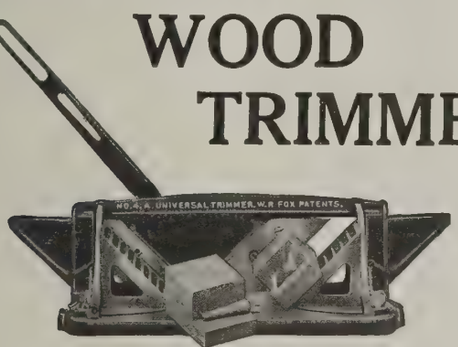
The Buffalo Crain Combination Wood Worker

Strong — Simple — Large Capacity

12 Operations in One Machine without any extra attachments.

Investigate and be convinced! For a thoroughly practical machine — substantial in construction and design, of ample capacity, low power cost, ease of operation, and dependability—you can't beat the Buffalo machine. It is a

Band Saw
Planer
Cut-off Saw
Shaper
Sizer
Rip Saw
Lathe
Boring Machine
Spoke Equalizer
Dado Head
Tenoner



combined in one compact machine. Three men can work at it at one time without interfering with each other. Practically every operation of daily occurrence in a carpenter and repair shop can be done on it. Made with 5″ or 10″ planer head. It is a great money maker and one of the finest investments a contractor, builder or carpenter can make. Let us send you some of the letters we receive from pleased customers almost daily. Complete description on request. *Ask for catalog No. 134-5.*

If you had made $15

more on each frame house you built last year, how much more would your profits have been? If you built ten houses, the saving would have been $150.

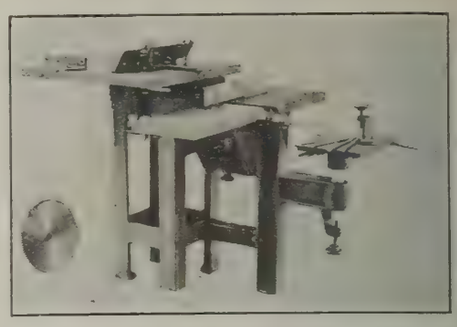
If you use

Wheeler Safety Scaffold Brackets

instead of old-style wood staging for scaffold, you can save that much this year and possibly more.

Is it worth saving?

We can proove our statement and will do so without expense to you. Will you try our Brackets? If you save money you will be glad you tried our plan. If you do not save, it will cost you nothing to make the trial. You will save during first year, three to five times what the brackets cost and have them to use year after year. They never wear out. **Write today for our trial offer**

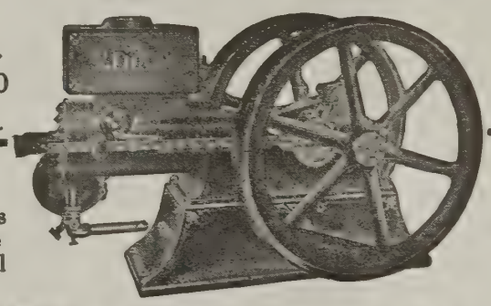


American Steel Scaffold Co., 50 McGraw Bldg. Detroit, Mich.

$95.00 BUYS 3 Machines { A SAW BENCH / AN 8″ JOINTER / A MORTISER AND BORER

This combination machine is the best value ever offered. It is made of solid cast iron and is furnished complete with necessary tools, belt, etc. Each machine is distinct from the others, and can be operated without interference with them.

You should send at once for literature. It tells all about this new machine.



THE TANNEWITZ WORKS, 41 S. Front St., Grand Rapids, Mich.

WE SELL GASOLINE ENGINES

5 H. P. $119.50

1¾-28 H. P.

30 Days Free Trial

Built for Service

CONTRACTORS AND BUILDERS ATTENTION

Galloway Engines are made in all sizes from 1¾ to 28 H. P. They run on gasoline, naphtha, kerosene or distillate. We are furnishing complete mixing rigs and our price means a big saving of money to you—$50 to $300, depending on the engine you buy. You have the privilege of trying the outfit 30 days. If it is in any way unsatisfactory we refund your money with interest and pay freight both ways.

The Galloway Gasoline Engine

SIMPLEST ENGINE BUILT

Only four things to do:

Turn on the switch, turn on the oil, turn on the gasoline, give the flywheel a start and the Galloway will go right along all day without further attention. It is ideal power for a small shop, and it's got the capacity to take care of your growing needs for operating planers—matchers, lathes, saws and concrete mixers.

The Galloway has been classed as a standard, high grade engine for fifteen years. Over 4,000 in use in Iowa alone. Thousands in every other State and Territory.

If you try the Galloway engine, you will find that it is not overspeeded. Remember, the bore and stroke count, and you don't have to drive your engine faster than you ought to drive it to get the rated horse power. Rated by actual brake test.

On the larger sizes, if it is not entirely convenient for you to pay all cash, we will take your note for the balance at the regular rate of interest for six months.

The price given is for the five-horse power only, but we make these engines in seven sizes.

Ask for free information on stationary and portable gasoline engines from two to twenty-eight horse power. We make the best, and we price them at a reasonable figure. Write today.

The William Galloway Company, 1695 Galloway WATERLOO, IOWA

Taylor Portable Steel Derrick, 2000 pounds capacity. Adjustable capacity and speed to three ways. One man operates both cranks and can hoist with ease 700 pounds. Weight 160 lbs. Made in two sections. A man can climb a ladder with either section. Beam section connects to post by tipping in a vertrcal position. Consider the durability of a derrick constructed of malleable iron and steel and that of wood, *more compact, more powerful.* Roller bearing circle swing. Clears side wall of building three feet. With special platform attachable to side of railroad gondola car for unloading water-pipe, etc. Price of derrick with three way block, brackets, and bolts for attaching to building, $40.00 f. o. b. Chicago.

Messrs. Smith & Seale, of Gloster, Miss., said they could not run their shop without the FAMOUS WOODWORKER

Here's Their Letter:

Gloster, Miss.

The Sidney Tool Co., Sidney, Ohio.

Gentlemen:—We have been using one of your No. 14 Universal Woodworking Machines, furnished with all attachments, for the past year and we believe it to be the most perfect woodworking machine on the market. Every attachment on this machine works perfect and does perfect work. We consider it the most up-to-date and complete machine ever made and we could not run a general repair shop without it.

We have not bought a buggy body, seat or wood part or gear, nor wagon axle, felloe round, bolster reach, or anything of the kind since we have had this machine. We buy our timber rough and cut out all such parts that we need, and we will be pleased to recommend this machine to any man running a general repair shop and will be pleased to answer any questions that any brother repair man should like to ask in reference to this machine.

Will endorse anything the Sidney Tool Co. has said in advertising this useful machine.

SMITH & SEALE.

SIXTEEN MACHINES IN ONE

1—27-inch Band Saw.
2—12-inch Jointer.
3—Saw Table, with raising and lowering arbor.
4—Single Spindle Shaper.
5—Boring Attachment, arranged on special boring spindle.
6—Pony Planer.
7—Tongue and Pole Rounder.
8—Hollow Chisel Mortiser.
9—Single End Tenoner.
10—Drum Sander.
11—Disc Sander.
12—Knife Grinder.
13—Emery Grinder.
14—Band Re-Saw.
15—Spoke Tenoner, Rim Borer and Wheel Equalizer.
16—Adjustable Felloe Rounder.

The No. 14 Famous

does the work of sixteen ordinary woodworking machines.

Your business pays the biggest profits when you eliminate millwork bills. You can do this by installing a No. 14 FAMOUS Universal Woodworker. Sixteen woodworking machines in one.

All the woodworking machinery you need is embodied in this one machine. It's not necessary to invest your capital in a *number* of machines when *one* is sufficient—when *one* does just as much as several and costs *less to buy and less to maintain.*

Over six hundred FAMOUS Universal Woodworkers are in use: and we are getting letters of indorsement every day. Not one has ever been returned; no user has ever found reason for dissatisfaction. Can any other universal woodworker show such a record? No, Sir!

Our guarantee covers the entire life of the machine. You take no chances whatever. Write for special terms and full particulars. Don't think you cannot afford one—you cannot afford to do without one. Write us today.

No. 6 "Union" Combination Saw

BUY A BAND SAW THAT IS DURABLE

CRESCENT

Band Saws satisfy those practical, experienced mechanics who need strong, substantial tools.

The reason CRESCENT Band Saws are so popular is because they have earned a well-deserved reputation for durability and accuracy where hard service is demanded of them. Each day they are pleasing some of the most exacting band-saw operators in every civilized country, and as you appreciate what it means to have a thoroughly dependable, well-built, practical band saw, you should certainly look into the merits of the CRESCENT line before you order.

Send for a catalog telling all about these splendid machines, and our line of Saw Tables, Jointers, Borers, Swing Saws, Planers, Planers and Matchers, Wood-Workers, Disk Grinders.

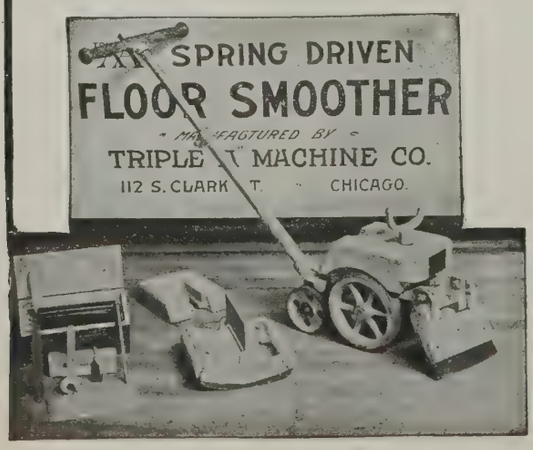
"IT'S A SCRAPER BUT IT WORKS LIKE A PLANE"

That is what the many satisfied Contractors and Builders who are using **The Boss Improved Floor Scraper** say.

THE BOSS has double swivel allowing the knife to be set in any position. Gauge can be set for any thickness of shaving and keeps knife from making depressions in floor. Gives knife double support. The pear-shaped wheel which is in the gauge is attached to the gauge in front so that when the scraper is let down to take shaving, it lets the knife down gradually and prevents the knife from making a deep cut. With this gauge and wheel attachment the knife will leave no mark. Impossible to do poor work. Adjustment simple—positive. Gauge can be removed instantly. Standing attachment cleans wheels and takes off the rosin when working hard pine. Prices very low. Write for descriptive circular "N"

GEORGE J. KEPPLINGER, - Dwight, Illinois



When You Buy a Floor Surfacing Machine
BUY A GOOD ONE—IT PAYS!

The Triple "A" Spring-Driven Floor Smoother combines the advantages of the hand machine and the power machine. No more expense than the former, yet has the capacity and ease of operation of the latter.

No wasted energy pulling a dead weight.

About half of all the Triple "A"s sold have been bought by owners of dead weight machines. What's the answer?

"Get the best first and save extra expense."

The Triple "A" to be appreciated needs only to be seen in operation.

For advertising purposes we will give a special discount on the first machine sold in each town.

A ROOF THAT OUTLASTS THE BUILDING

No one knows how many centuries Asbestos has been exposed to the elements without deterioration. And Cement and Stone (Concrete) construction dates back to the time of the Romans, many of whose works are still in perfect preservation after a test of nearly 2,000 years. Both Asbestos and Portland Cement are practically everlasting.

J-M Transite Asbestos Shingles are composed of these **indestructible** minerals. They are made by moulding pure Asbestos Fibre and Portland Cement into one homogeneous mass under hydraulic pressure. There are no layers or laminations to separate in

Baraga High School, Baraga, Mich.
Covered with J-M Asbestos Shingles

J-M TRANSITE ASBESTOS FIRE-PROOF SHINGLES

These asbestos, or stone, shingles are not affected by acids, gases or chemical fumes. Continued weather changes have no effect on them. Freezing and thawing hasten the setting of the binding material. The more severe the weather conditions, the stronger and harder these shingles become. They never rot or decay; never warp or split. Do not break like slate and are at least 15% stronger than laminated Asbestos shingles. Are absolutely fireproof. And, like all stone, they never need paint or protection of any kind to preserve them.

Come in sizes and shapes to meet all conditions, and in colors of natural gray and Indian red.

PATENT APPLIED FOR

NICHOLLS NEW TAKE-DOWN SQUARE

Guaranteed Accurate and Will Remain So

The main feature of our new Take Down Square is that it will always stay true; it is so constructed that the tongue is held down into beveled bearings by a spring, and these bearings are made so as to take up the constant wear which comes in taking square apart and putting it together, thereby producing constant accuracy.

SOME OF ITS GOOD POINTS:

1. Convenient to carry.
2. Each time Square is taken apart and put together the wear produces a firmer joint, thereby insuring constant accuracy.
3. No screws used; locks automatically.
4. The only Take-Down Square which leaves no part of the Tongue attached to body, when separated.
5. Occupies smaller space than any other Take-down Square manufactured. 2″x24″.
6. Instantly taken apart and put together.
7. Rust-proof canvas case with each square.

Manufactured in Nos. 3 and 100 Standard; also No. 100 Rafter Framing, giving lengths of common, hip, valley, and jack rafters for 17 different pitches of roof.

ALSO THEIR CUTS

If your dealer will not supply you we will gladly ship you one of these express prepaid upon receipt of price.

You Can Pay for the Mixer on a Single Job by the Greater Economy of Operation

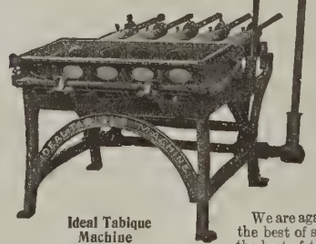
It is not alone the saving of one-third in first cost, one-half in power, one man to operate the hoist and two-thirds the delays and repairs, but the greater portability enabling it to always be kept at the most convenient position on the job for rapid work, that are the distinguishing features of the

Eclipse Concrete Mixer

And we offer our patrons not only greater economy of operation, but unequalled service in shipment. We carry 100 Eclipse Mixers in stock at our factory, stores, warehouses and branch houses for immediate shipment.

It is pre-eminently the mixer for the contractor because it saves money in nearly every possible use.

Our new 1911 catalog No. 32 is just off the press and gives full information how to handle the Eclipse to obtain best results. Write for it. Our testimonial booklet explains how other contractors are making money by using the Eclipse Mixer.



You can buy the small size Eclipse Batch Mixer Complete with Power at a lower price than a Continuous Mixer.

AT LAST
A TILTING BATCH MIXER
FOR LESS THAN THE COST OF A CONTINUOUS

THE LITTLE WONDER

Capacity, three to four feet. Turns out a better quality of concrete than can possibly be obtained by hand mixing and at one-twentieth of the labor cost.

Just the mixer for sidewalk or small foundation work, floors, etc.

Simplest mixer built. No sharp corners in drum to catch concrete. Convenient side dump. Low charge. Charges or discharges while running at full speed. Mixes wet or dry material equally well. Can be set over sidewalk forms, eliminating wheeling. Equipped with one horse power gasoline engine will turn out more concrete than machines costing twice or three times as much. Can be operated by hand.

Furnished on skids or on trucks with or without power. Write for descriptive literature. Made by the manufacturers of THE GREAT POLYGON LINE.

WATERLOO CEMENT MACHINERY CORPORATION
111 VINTON STREET WATERLOO, IOWA

Big Profits In Concrete Specialties

Do you realize that there is a lot of money in some sand bank waiting for you to take it out? Do you know that every wagon load of sand can be made to produce a net profit of $25? It is a fact, and right at your very door is a golden opportunity to coin money in a most rapid and gratifying manner. Just as an example of what can be done in this line we give below one man's experience and profits for one week.

The manufacture of ornamental concrete articles is not difficult and can be accomplished by any man of ordinary intelligence. We furnish complete and detailed instructions with every mould. These moulds can be readily sold for use in city parks, lawns, cemeteries and to every property owner. Do you know of another line that will net you such handsome returns in so short a time as the manufacture of these articles?

Figure the Profit Yourself

12 lawn vases, easily sell for $5.00 each	$ 60.00
33 hitching posts, easily sell for $5.00 each	165.00
	$225.00

They Cost as Follows:

41 sacks cement (10¼ bbls.) at $2.00 per bbl.	$20.00	
5 yds. sand, $1.00	5.00	
57 hours labor, 20c	11.40	
33 staples and rings for posts, 10c	3.30	$40.00
A good week's profit		$184.80

Indestructible, Solid Substantial Hitching Post

These moulds never sell for less than $5.00 each, which is much less than the cheapest iron hitching post or vase you can buy and are much more beautiful and more durable. They easily bring from $15.00 to $25.00 a pair.

Everything in the Concrete Machinery Line

Every carpenter, builder, contractor, mason and property owner should have a copy of our 1911 concrete machinery catalog. PRACTICAL BOOKS FOR THE BUILDING TRADES

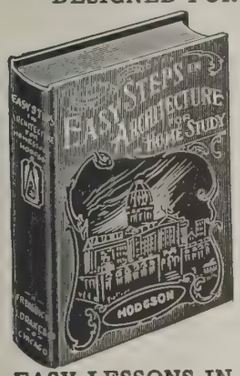
THE STEEL SQUARE—TWO VOLUMES. A PRACTICAL TREATISE ON THE USES OF THE STEEL SQUARE. By Fred T. Hodgson. 600 Pages, 500 Illustrations.

Two Vols., Cloth Binding. Price.....**$2.00**
Single Vols., Part I, Cloth. Price..... **1.00**
Single Vols., Part II, Cloth. Price..... **1.00**

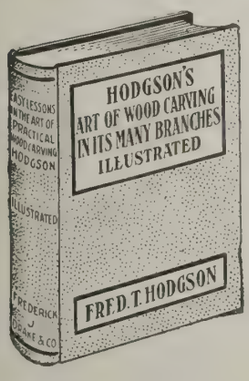
Mr. Hodgson was the first—as well as the last—person who has written on this important tool, and the two volumes now issued contain the earliest and the latest up-to-date methods of applying the STEEL SQUARE for the solution of the many problems this wonderful instrument can solve when in capable hands. The two volumes, named herewith, contain about all that is possible to be done with the square, that is of practical value to the workman, and, as they show nearly all the simple, as well as the difficult things, that can be accomplished with the aid of this tool, there will be little trouble for the workman to work out any minor problem that may confront him, if it is within the purview of the tool. In short, the two volumes contain all that can now, or hereafter, be accomplished with the square. They are profusely illustrated with diagrams, and explanatory sketches, which cover the whole ground of steel square practice. Two volumes of the greatest possible value to the young carpenter.



BUILDERS' ARCHITECTURAL DRAWING SELF-TAUGHT. By Fred T. Hodgson. F. A. I. C. 336 Pages, 250 Illustrations and 18 Folding Plates, 12mo, Cloth Binding. Price.....**$2.00**

This work is especially designed for carpenters and for students of architecture, woodworkers and others who desire to learn drawing at home, and who have not the means, time or opportunity of taking a regular course in school, or college, nor of availing themselves of the offers made by one or other of the "Correspondence Schools."

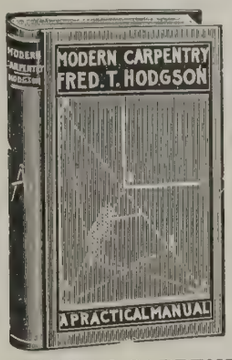
The work commences with a description of drawing instruments and accessories, with rules for using them, and hints as to their care and management. Rules for laying out simple drawings and executing same are given, and the student is taught step by step to draw to scale, first the plans, next the elevations, and finally the details of a cottage, including foundations, walls, doors, windows, stairs and all other items required for finishing a small building complete in every particular.



EASY STEPS TO ARCHITECTURE. PARTICULARLY DESIGNED FOR HOME STUDY. By Fred T. Hodgson, F. A. I. C. 350 Pages, 230 Illustrations, 12mo, Cloth Binding. Price .**$1.50**

As every mechanic employed in the building trades must necessarily have some knowledge of architecture, a book of this kind will be found by him to be a great assistance in acquiring such knowledge without a great expenditure of effort. A part of this work has been for years a sort of text-book in schools where architecture is taught, and is a catechism to some extent. The questions and answers are easily understood and as easily remembered.

The second part of the book deals more particularly with architectural styles, while the first part is mostly devoted to the classic orders, Greek and Roman. Full explanation of the latter styles are made, and illustrations show these styles and give a brief history of their growth and decay.



EASY LESSONS IN THE ART OF PRACTICAL WOOD CARVING. By Fred T. Hodgson, F. A. I. C. 284 Pages, 200 Illustrations, 12mo, Cloth Binding. Price.....**$1.50**

This work, "Easy Lessons in Practical Carving," is prepared in the same happy, easily understood style of writing that has made the name of the author so famous among the working men of English-speaking countries.

The lessons given in this new book begin at the very beginning of carving and lead the young workman by easy steps through the mazes of the art, until he is able to turn out work of a creditable character. The use and care of carvers' tools are given and explained, and the tools described and shown in illustrations, with methods of sharpening and honing the tools, in a clear and interesting manner. All necessary appliances are shown, described, and illustrated, both for holding the work, and for preparing the tools and finishing up the carvings. The various styles of carving are fully explained, such as flat carving, chip carving, incised carving, scratch carving, figure carving, carving in relief, round carving and jewelry carving.

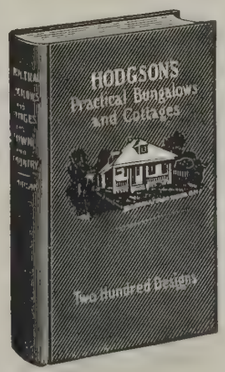
MODERN CARPENTRY AND JOINERY—VOL. I. By Fred T. Hodgson, F. A. I. C. 300 Pages, 318 Illustrations, 12mo, Cloth Binding. Price.....$1.00

This is a real modern work, and the large numbers of it that have been sold (over one million) is an evidence that American workmen have found in it the things they expected. It is one of the best books of the kind ever brought out for teaching the young workman the art of correct and easy wood-working. It shows how to lay out roofs, rafters, stairs, hoppers, bevels of all kinds, mitering, coping, circle work, flooring, splayed work, plain stairs and hand-railing, cornicing, dove-tailing and many other things the young carpenter will require to know in the performance of his regular work. It is written in a very simple style, and can be understood by any person who can read every-day English. Unlike other works prepared for workmen, it is void of bewildering formulae and algebraic puzzles, and the reader is not asked to wade through long mathematical calculations to get at the kernel of the subject before him. The work contains some 300 illustrations and diagrams, all of which are explanatory and instructive.

MODERN CARPENTRY AND JOINERY—VOL. II. ADVANCED SERIES. By Fred T. Hodgson, F. A. I. C. 400 Pages, 300 Illustrations, 12mo, Cloth Binding. Price.. .....$1.00

This volume is somewhat similar to Vol. I, only on advanced lines, and is intended to follow up the progress made by a study of the first. Indeed, it is simply a continuation of the first volume, on a higher plane, and no workman having mastered the contents of one, will rest satisfied, until he has also mastered the contents of the second volume.

This volume contains some examples of work, with a description of the way the work is performed, and the materials employed. Many very difficult problems are here shown and the solutions and explanations are given and fully explained, many things that at first seem formidable to the unpracticed workman, become quite easy of solution under the magic wand of the author's method of explanation.



COMMON SENSE STAIR BUILDING AND HAND-RAILING. By Fred T. Hodgson, F. A. I. C. 300 Pages, 300 Illustrations, 12mo, Cloth Binding. Price.....**$1.00**

This is an excellent work for the young carpenter who is ambitious of becoming an expert in hand-railing and stairbuilding, inasmuch as it commences at the very beginning of the art, and shows how to lay off a stair on the floor, placing the newels, laying off treads and risers, strings, winders, wells and flyers.

The object of the author is to lead the student step by step, in such a way that he takes in the whole art of stairbuilding before he is aware of it. This is decidedly the best and most practical work on stairbuilding in the market, and just what the untrained workman wants. The part of the book devoted to handrailing exhibits three different methods of laying out and working handrails suitable for any kind of stairs, straight, circular, elliptical, or for stairs with landings, doglegged, newels, or cylinders. These systems of handrailing have been taken from the best sources on the subject, and have been revised and edited in the most careful manner.

PRACTICAL BUNGALOWS AND COTTAGES FOR TOWN AND COUNTRY. Arranged and Edited by Fred T. Hodgson, assisted by E. N. Braucher, Architect. 12mo, Cloth, 420 Pages, 400 Illustrations. Price.....**$1.00**

This work contains perspective views and floor plans of over two hundred choice bungalows, cottages, houses and flat buildings, selected with great care to combine architectural beauty, convenience and economy of construction, ranging in prices from $500.00 to $3,800.00. Every plan shown is made by a licensed architect and has been built from, to the entire satisfaction of the builder and within the estimated cost. This work will be found invaluable to the home builder, furnishing many new and up-to-date ideas and suggestions in modern architecture. The number of California bungalows, which the editors have taken great pains to select, are without question the most attractive modern low cost homes ever built. We are prepared to furnish blue prints at a very moderate cost, ranging from $5.00 to $15.00, according to cost of erection, consisting of floor, roof and foundation plans, front, side and rear elevations, with complete type-written specifications.

Any of the above books sent Post or Expressage Prepaid on receipt of price.

New Books for Building Mechanics

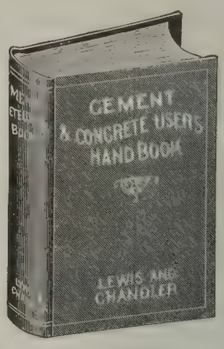
MODERN PLUMBING ILLUSTRATED. By R. M. Starbuck.

This book represents the highest standard of plumbing work. It has been adopted and used as a reference book by the United States Government, in its sanitary work in Cuba, Porto Rico and tne Philippines, and by the principal Boards of Health of the United States and Canada.
It gives connections, sizes and working data for all fixtures and groups of fixtures. It is helpful in demonstrating and in figuring work. It gives the mechanic quick and easy access to the best modern plumbing practice. Suggestions for estimating plumbing construction are contained in its pages. This book represents, in a word, the latest and best up-to-date practice, and should be in the hands of every architect, sanitary engineer and plumber who wishes to keep himself up to the minute on this important feature of construction. 400 octavo pages, fully illustrated by 55 full page engravings. Price.....**$4.00**

STANDARD PRACTICAL PLUMBING. By R. M. Starbuck.

A complete practical treatise of 450 pages covering the subject of Modern Plumbing in all its Branches, a large amount of space being devoted to a very complete and practical treatment of the subject of Hot Water Supply and Circulation and Range Boiler Work. Its thirty chapters include about every phase of the subject one can think of, making it an indispensable work. Fully illustrated by 347 engravings. Price.....**$3.00**

PRACTICAL STEAM, HOT-WATER HEATING AND VENTILATION. By A. G. King.



This book is the standard and latest work published on the subject and has been prepared for the use of all engaged in the business of steam, hot water heating, and ventilation. It is an original and exhaustive work. Tells how to get heating contracts, how to install heating and ventilating apparatus, the best business methods to be used, with "Tricks of the Trade" for shop use. Rules and data for estimating radiation and cost and such tables and information as make it an indispensable work for everyone interested in steam, hot water heating and ventilation. It describes all the principal systems of steam, hot water, vacuum, vapor, and vacuum-vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation and the fan or blower system of heating and ventilation. 367 pages. 300 detailed engravings. Price.....**$3.00**

CONCRETE CHIMNEYS, SLATE AND ROOF TILES. By A. A. Houghton

The manufacture of all types of concrete slate and roof tile is fully treated. Valuable data on all forms of reinforced concrete roofs are contained within its pages. The construction of concrete chimneys by block or monolithic systems of is fully illustrated and described. A number of ornamental designs of chimney construction with molds are shown in this valuable treatise.....**50 Cents**

POPULAR HANDBOOK FOR CEMENT and CONCRETE USERS. By Myron H. Lewis

This is a concise treatise of the principles and methods employed in the manufacture and use of cement in all classes of modern works. The author has brought together in this work, all the salient matter of interest to the user of concrete and its many diversified products. The matter is presented in logical and systematic order, clearly written, fully illustrated and and free from involved mathematics. Everything of value to the concrete user is given, including kinds of cement employed in construction, concrete architecture, inspection and testing, waterproofing, coloring and painting, rules, tables, working and cost data. Price.....**$2.50**

ORNAMENTAL CONCRETE WITHOUT MOLDS. By A. A. Houghton.

The process for making ornamental concrete without molds, has long been held as a secret and now, for the first time, this process is given to the public. The book reveals the secret and is the only book published which explains a simple, practical method whereby the concrete worker is enabled by employing wood and metal templates of different designs, to mold or model in concrete any Cornice, Archivolt, Column, Pedestal, Base Cap, Urn or Pier in a monolithic form—right upon the job. These may be molded in units or blocks, and then built up to suit the specifications demanded. This work is fully illustrated with detailed engravings Price.....**$2.00**

CONCRETE FROM SAND MOLDS. By A. A. Houghton.

A practical work treating on a process, which has heretofore been held as a trade secret by the few who possessed it, and which will successfully mold every and any class of ornamental concrete work. The process of molding concrete with sand molds is of the utmost practical value, possessing the manifold advantages of a low cost of molds, the ease and rapidity of operation, perfect details to all ornamental designs, density and increased strength of the concrete, perfect curing of the work without attention and the easy removal of the molds, regardless of any undercutting the design may have. 192 pages. Fully illustrated. Price.....**$2.00**

CONCRETE WALL FORMS. By A. A. Houghton.

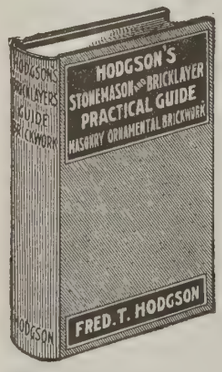
A new automatic wall clamp is illustrated with working drawings. Other types of wall forms, clamps, separators, etc., are also illustrated and explained.....**50 Cents**

CONCRETE FLOORS AND SIDEWALKS. By A. A. Houghton.

The molds for molding squares, hexagonal and many other styles of mosaic floor and sidewalk blocks, are fully illustrated and explained.....**50 Cents**

CONCRETE SILOS. By A. A Houghton.

Complete working drawings and specifications are given for several styles of concrete silos, with illustrations for molds for monolithic and block silos. The tables, data and information presented in this book are of the utmost value in planning and constructing all forms of concrete silos....**50 Cents**



MOLDING AND CURING ORNAMENTAL CONCRETE. By A. A. Houghton.

The proper proportions of cement and aggregates for various finishes, also the methods of thoroughly mixing and placing in the molds, are fully treated. An exhaustive treatise on this subject that every concrete worker will find of daily use and value.....**50 Cents**

Any of these books sent prepaid on receipt of the price. Address **NATIONAL BUILDER, Pontiac Building, CHICAGO, ILLINOIS**

The 20th Century Bricklayers and Mason's Assistant

By FRED T. HODGSON

This work is in two parts combined in one volume, the first part being devoted altogether to brick work of all kinds; and this includes an explanation of the various terms employed in the trade with illustrations and definitions showing what the terms really mean.

There is a chapter on Foundations which goes into the matter at great length, and is fully illustrated and explained, and which shows how to lay out and prepare any kind or shape of foundation.

Damp courses are dealt with in a separate chapter in which the various methods of constructing damp courses are fully illustrated, described and explained are shown. Various methods of forming brick pilasters, columns, quoins and pands are explained, illustrated and described. Joints in brick work are illustrated, described and explained in a separate chapter in which the kinds of mortar to employ for various works are defined. Chimney breasts, flues, stacks, fire-places and chimneys of all kinds are described and illustrated.

Brick bonding for all sorts of work is shown and illustrated by a large number of diagrams and the manner of bonding is fully explained. Brick arches of every kind, gauged and ungauged, are explained at length, and a large number of illustrations are shown, giving methods of describing the arches and obtaining the joints for same. Bay and oriel windows are discussed and the methods of working them are shown and described both by text and diagrams. Methods of measuring brickwork, pointing, concrete and other matters for the estimator are fully described. The tools used by the bricklayer and his helpers are fully illustrated and described. Bricklayers' mortar and other useful memoranda close Part One of the book.

Part Two deals with the stone mason's work altogether and opens with a chapter on definitions of technical terms used in masonry. Tools and appliances are fully described and as fully illustrated, with explanations and methods of using them. The trade names of wrought stones are given with illustrations showing the work in progress and in a finished state; also methods of working them. Methods of building walls in rustic rubble, ashler square, uncovered, random coursed, irregular corners, snecked and squared rubble, picked polygonal ragwork and other styles of work are explained and illustrated. Finished stones such as window sills, window heads, copings, arch stones, key stones and other dressings are described and illustrated. Stone arches and joints are described and illustrated, with ample instructions for working them. A chapter on preparing stone steps and stairs is given, along with complete diagrams and instructions showing how the work is done. There is also a chapter explaining the method of building a circular headed window or door in a circular tower or other circular wall. A chapter on estimating stone work, with a copious specification is also included along with a short treatise on building skew arches and skew bridges, and which is illustrated with a large number of diagrams and working sketches, showing how to do the work in a proper manner. This part is illustrated with over 200 working drawings and diagrams.

The whole work contains over 450 fine illustrations and diagrams, and is complete cyclopedia of practical instructions in brick-work and masonry and must prove of inestimable value to the operative bricklayer and mason. 12 mo., cloth, price, $1.50; half leather $2.00.

The Business of This Place is to Raise Salaries

From every section, and from all sorts and conditions of men, messages come to tell of earnings increased and futures brightened through study of I. C. S. Courses.

One letter gives the romance of a young man in California that began with little or no education; another tells the story of a high-school graduate in Maine that found himself educated for everything but to make a living. Here are the heart-throbs of a fellow that toiled 12 hours a day and studied his Course as best he could; there is the experience of a clerk or office hand with plenty of spare time and the will to use it. Now we read of some one whose pay was a mere pittance; now of a foreman or superintendent that enrolled because his ambition aimed at still bigger things.

All sought betterment through knowledge and found it. All are enthusiastic. All remember with pleasure the day they marked and mailed an I. C. S. Coupon.

And no matter where you live, how little spare time you have, or how brief your schooling, the I. C. S. can raise **your** salary. That statement is backed with 20 years of success and a record of countless successes. The 400 or more advancement letters received every month represent only a fraction of the total number of advancements.

I. C. S. Courses have made draftsmen, foremen, and superintendents of shop hands; building contractors, architects, structural and concrete engineers of carpenters and masons; advertising men, window trimmers, show-card writers, chemists, illustrators, and designers of clerks; electrical, mechanical, and steam engineers of laborers; mine inspectors, foremen, and mining engineers of mine workers; bridge engineers, surveyors and mappers, civil engineers, gas engineers, automobile runners, and civil service employes of young men willing to use their spare time to mold a career.

Suppose you were to increase your earnings only $20 a month—what a fine return that would be on your investment! G. O. Gibboney, of Mount Pleasant, Pa., increased his earnings $250 a month, and hundreds have done as well.

Mark and mail the Coupon and learn how the I. C. S. can raise YOUR salary.

International Correspondence Schools

NATIONAL BUILDER DESIGN No. 342

Perry and Thomas, Architects, Chicago

For Floor Plans, Elevations and Details, See Supplement Sheet of this number. Estimated Cost, $10,498.78

THE WALSH APARTMENT HOUSE

Our supplement sheet for June shows a two-story apartment house recently built in Chicago for Mr. James C. Walsh from the plans of Perry & Thomas, architects.

Pressed brick with Bedford stone trim for the exterior form a pleasing combination, with an air of solidity due to the absence of projecting metal or wood cornices.

Access to the second floor apartment is provided by an open stairway in the public hall, from which opens the door to first floor apartment. Each compartment has a porch entirely separate from the entrance porch.

Each apartment is unusually complete, the living rooms having brick mantels and built in bookcases, the dining rooms having sideboards, and each of the four bedrooms in each apartment having a large closet, besides the hall coat closet, linen closet and medicine cabinet in the bathroom.

Being built on a corner lot allows excellent light and ventilation for every room. The building is finished in hardwood throughout and heated by hot water. Laundry facilities are provided in the basement, besides which there is ample storage room.

Total estimate	$10,498.78

Estimated cubic feet of building from bottom of cellar to roof, not figuring in rear porch, 60,588, which makes the cost of this class of building rate about 17c per cubic foot.

A CANON OF ETHICS FOR ARCHITECTS

The following canon of ethics has been adopted by the American Institute of Architects as a general guide to members, and will be recognized as enumerating some of the elementary duties of an architect towards fellow professional men:

It is unprofessional for an architect,

1. To engage, directly or indirectly, in any of the building trades.

2. To guarantee an estimate or contract by bond or otherwise.

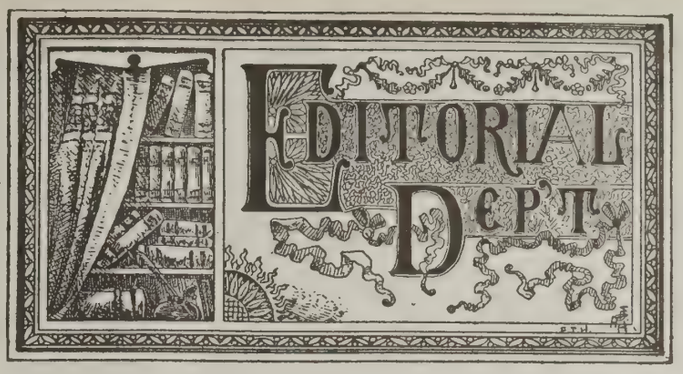
3. To accept any commission or substantial service from a contractor or from any interested party other than the owner.

4. To advertise.

5. To take part in any competition the terms of which are not in harmony with the principles approved by the institute.

6. To attempt in any way, except as a duly authorized competitor, to secure work for which a competition is in progress.

7. To attempt to influence, either directly or indirectly, the award of a competition in which he is a competitor.



8. To accept the commission to do the work for which a competition has been instituted if he has acted in an advisory capacity either in drawing programme or making award.

9. To injure falsely or maliciously the professional reputation, prospects, or business of a fellow architect.

10. To undertake a commission while the just claim of another architect who has previously undertaken it remains unsatisfied, or until such claim has been referred to arbitration or issue has been joined at law.

11. To attempt to supplant a fellow architect after definite steps have been taken toward his employment.

12. To compete knowingly with a fellow architect for employment on the basis of professional charges.

To provide for the future is the duty of every man who has a family, or who expects to have one.

* * *

The recent movement being made in England to have every man who works for a living, protected by an old age pension, is a step in the right direction.

* * *

The British Government is also about to enact such laws that may be necessary to ensure a regular weekly or monthly payment in a case of sickness, accident or permanent injury. The money for this purpose is to be provided by a fund, a portion of which is to be raised by each workman contributing about one cent a day, from his wages, which is retained by the employer, who hands this, with a like amount to the government, which also adds to it a like sum, or about one-third of the whole amount collected.

* * *

Proper machinery is provided by the government for the collection and disbursement of these monies, and the whole is placed under the control of the National authorities, a step which will insure the nearly perfect working out of the whole scheme. This law, in connection with the old age pension enactments, will go a long way towards lessening abject poverty in the old land, if it does not encourage a tendency towards idleness and dependence. This policy is a step in the direction of socialism, a condition towards which the world seems to be rapidly drifting.

* * *

The following figures showing the working of the German workmen's insurance law in 1909 are of interest to American workers: Of a total population of 63,879,000 people, 9,938,478 males and 3,456,812 females were insured against the consequences of illness. They were insured in 23,449 insurance offices in all parts of the empire. Against accidents were insured 14,854,000 males and 8,913,000 females. Against complete invalidity, or inability to work, were insured 10,707,100 males and 4,737,200 females. There were 5,540,825 cases of illness dealt with, 1,021,168 cases of accident and 115,264 fresh pensions for invalidity in addition to the existing 983,354 pensions. Old age pensions numbered in all 130,643. The income from insurance was 891,598,800 marks (four marks equal roughly $1), of which 413,497,700 marks were contributed by the employers and 342,076,300 by the workmen. The imperial contribution was 51,500,700 marks. The total expenditure was 598,924,200 marks.

John Passmore Edwards, who died at the age of 87 a few weeks ago, was one of the best known of English philanthropists. He made a great fortune, but he has probably died a poor man, most of his wealth having been devoted to the establishment and endowment of libraries, convalescent homes and other charitable institutions. The son of a working carpenter, he made his way to wealth and position by sheer industry and pluck. No sooner was he on the high road to success than a long illness took him away from his publishing business, with the result that he was forced into bankruptcy. On his return to business he denied himself everything until he could call his creditors together and pay them all twenty shillings in the pound.

In 1876 he bought the Echo, started the first one cent newspaper in London, and rigorously excluded all mention or reference to betting and horse racing. In spite of that the paper was soon a success and made him a fortune. At one time he sold the controlling interest in the paper to the Storey-Carnegie combination, which aimed at establishing a chain of Echos covering a good part of the United Kingdom. In less than three years he bought the Echo back at an enhanced price, and the Storey-Carnegie com-

bination was at an end. He was the mainspring in the Building News Company, and succeeded in making that journal one of the leading architectural papers of the world. He was the first to introduce the art of lithography in architectural journalism.

* * *

Gold bricks, real ones, may be the means of restoring the ancient fame of Golconda, near Hyderabad, in southern India, once known all the world over for its gold mines, but now a decayed city. The natural pits from which many centuries ago the precious metal was extracted have in course of time filled up with water. A contractor recently obtained permission to make bricks near the place and ten kilns were erected. The first finished bricks aroused curiosity by their yellowish tint, and analysis proved that they contained gold dust. On the basis of the yield of the sample bricks, the ten kilns will aggregate in weight about 12,857 pounds of gold, worth about $2,500,000. The site of the find belongs to the Nizam, or native ruler, whose affairs are administered by a British secretary, who has worked hard for nine years to produce a surplus in the Nizam's last annual budget of $15,000,000. It looks insignificant now compared with the result of nine days brickmaking.

* * *

Many eulogies have been written about the Taj Mahal at Agra, but perhaps the best is that recently given by Sir Frederick Treves. "Everyone," he says, "who visits Argamand Banu's tomb for the first time approaches it with curiosity, tinged probably by a faint disposition to be hostile. So much has been written about this wonderful building, so much rhapsody has been lavished upon it, that there is some suspicion of overpraise. The claim that it is the most beautiful building in the world is a claim that many at once resent. Its outlines are familiar enough from pictures and models, and it may be that they hardly warrant unrestricted ecstasy. The visitor proposes to himself to put sentiment aside and review the building critically . . . . to submit it to a common-sense inspection, for he is inclined to believe the Taj Mahal to be a much overrated monument. With the first sight of it there comes only a sense of indefinable pleasure; it is no mere feeling of admiration, still less of amazement. No mere delight in a splendid building, because it does not impress one as a building. There is a sudden vision, and with it a sudden sense of ineffable satisfaction, as if in the place of a marble dome the garden had been filled with divine music. All intended criticism is forgotten; there is nothing that appeals to the judgment or that suggests the weighing of opinions. There is merely a something that touches the nest sense of what is tender, beautiful, and lovable—a white cloud, luminous, intangible, translucent! The secret of the beauty of the Taj Mahal lies in the great arched recesses or vaulted alcoves which burrow deep into the body of the building. These are throbbing with sensitive shadows, and they give the impression that the onlooker can see into the very heart of this gentle palace as one would gaze into the heart of a yellow rose, where leaf by leaf the tints become deeper, warmer, and more living. There is ever a sense of something half hidden and half revealed, of a tenderness which has deeper depths. It is this abiding suggestion which makes the peculiar glory of the Taj a glory which is beyond the reach of any picture or any model. To many the Taj will be the most beautiful building in the world, while there must be few who would not acknowledge that it is the most lovable monument that has ever been erected."

CONTRACTING

By WARFIELD WEBB

THERE is more real economy in having efficient office help than in trying to get along with men whose ability is moderately good. A contractor who is conscious of this fact is the man who makes progress that is helpful. Sometimes we find a builder who is desirous of making as much profit for himself as is possible on every contract that he takes, and one means to attain this end is the employment of inferior workmen. He labors under the impression that with his own assistance he can not only show them much that will be helpful, but that he can do a great deal himself, and in this way keep the cost down.

For many reasons this is a most foolish notion. It might prove helpful sometimes in the case of a very ordinary piece of work, but even then the errors made, time lost, and other annoyances really foot up more than the additional profit would be by employing the best help. There are some contractors who are so narrow in their views on this important question that they are short-sighted enough to feel they are actually making a nice profit when they are losing money.

There is also the question of cheap construction work. Of inferior building. Some builders, particularly those who construct buildings to sell, have the habit of using only inferior materials, and the most inferior labor. In order to hide the defects that are natural in such cases, they hide them with paint and paper. We once heard a remark made about a party who had this method of constructing his houses. It was to the effect that his buildings could not be depended upon, from the simple fact that they were very cheaply constructed, and the defects covered with paint and wall paper. While it is true that he sold a fair number of them, the reputation that was spreading about him and his work was sure to sooner or later ruin his business and his reputation as well.

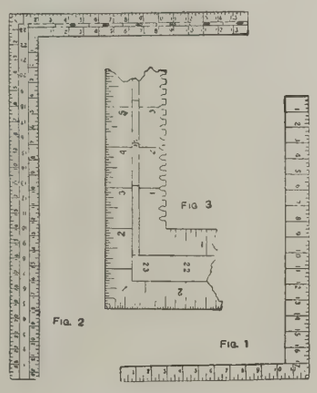
There is another class of house constructors who work upon lines that are slightly different from the above, but which are in no respects more honorable. They use scrap lumber, cheap brick and other materials that are worse than second hand, and then offer them as first-class houses, while some of the defects are actually in evidence. Many times the buyers are poor people who have only a small cash payment to make and the rest is purchased on time payments, with large interest. The contractor gloats over the deal he has made, and if the purchaser is not satisfied with the house he tells him to get out, and shows him his contract, which is so worded that the purchaser has no redress. If he moves out the contractor is just that much ahead. He sells it to another at the original price, sometimes for cash or on the same terms. In any event he is the gainer.

Instances of this kind are far more common than many would like to believe possible. What is the reputation of the builder of this class of work worth? He does not care, and no one else should. But there is the danger of distrust that is shared by many other contractors who are honest. It is a grave error to use inferior materials, or to employ inferior help. The economy in this way is not only false, but it is a mill stone to drag to ruin the unwise contractor.

Unless you are able to oversee the work of construction yourself the greater portion of the time, it would be a wise thing to employ a foreman that is capable of doing so, and upon whom you can depend. In doing this you will have to pay a good wage. Men of ability are not to be had for the asking, and the fact that they are always in demand is a further evidence of their value in a special line. With a competent foreman on the job, and with men under him that are capable, there is every reason to feel that they will do their work in a way that will be valuable to you.

In figuring on any contract it is far safer to allow enough margin for profit to make sure of your losses from unseen and undreamed causes. If you are so anxious to secure a contract that you will take it at a loss, then you had better give up contracting and go to work by the day. In the end you will find that you have gained, both in money, wisdom, and saved yourself much worry. How often, in order to beat a competitor, or to keep a force of men at work, or for some other reason equally as unwise, will not a contractor take a job at a figure that will make it almost impossible to obtain a profit.

Ignorance of the conditions governing a contract is sometimes responsible for this; then on other occasions, it is ignorance on the part of the contractor himself as to the duties demanded of him. In either event it is well to leave it to some one else, and not take a chance that has so much of the gamble in it. It is these little points that are at times most valuable for the contractor to bear in mind. The wise contractor will see ahead of him, and not simlpy live from day to day, taking every possible opportunity that savors of chance, in order to seek and make an imaginary profit for himself.



THE USE OF THE STEEL SQUARE

By J. H. B.

THE following is taken from The Building World, and gives some idea of the manner in which the Englishman at home makes use of the steel square for some purposes: Roofing by means of the steel square is doubtless now well known to many people—at least, by hearsay. The purpose of these articles is to show the methods of using the square to the best advantage. In the course of them more complete information will be given than any hitherto published, and this will be presented in a new and totally different manner. To attain this end more satisfactorily, the exact methods to be used, by which the various lengths, bevels, etc., are obtained, will be shown with the aid of photographs of the actual roofs dealt with. These will give more exact detailed assistance than is possible when drawings only are used.

Although the steel square (which emanated from America), has been in use for many years, there are still a great many who have never seen one, and who, when the tool is mentioned, confuse it with the old fashioned iron square, used for rough work, especially in the south of England, from time immemorial. Now there can be no doubt that the old fashioned carpenter's friend is really the forerunner of the modern tool, the latter being evolved from the former by our enterprising cousins across the water, the result amply repaying the troubles taken in doing so.

For the information of those who have not seen an up-to-date steel square, and also for those who are not familiar with the old style, a sketch of each is given, Fig. 1 showing the old and Fig. 2 the new. The former, as shown, consists of one arm, 1½ ft. long, usually 1½ in. wide, from one end of which branches off at right angles the shorter arm, 12 in. only in length by 1 in. wide. The

square thus formed is divided into inches, these being further subdivided into eights on the outer edge only (in the the drawing the inches are divided into quarters only); thus it is not convenient for measuring from the inside, the necessity of subtracting the width of the arms from the distance figured on the square being productive of mistakes. To these faults may be added that, owing to the comparative weakness at the angle, and the rough usage to which the tool is often put, it is rare indeed that one of these squares can be found which is a square in reality. The width of the two arms is also, as a rule, only approximately correct; the edges are not made straight, and can be depended upon only for the roughest of work, and will not by any means do for use in roofing by the methods to be dealt with here.

Coming to the improved square, as shown in Fig. 2, the longer arm is 2 ft. and the shorter 1 ft. 4 in. long, the former being 2 in. wide and the latter 1½ in. only. Each is divided into inches, these being again subdivided into sixteenths and numbered so as to read correctly from either end.

Each arm of the square is also divided, so that measurements can be read from the angle, thus adding considerably to the convenience when in use. In some makes of these squares, both arms are divided on the inside the same as the outside; but in the one used for the purpose of these articles, the longer arm is divided up into eighths only on the inside. The short arm is divided into inches, as shown in Fig. 2, and figured from the inside angle, the whole length being cut away at intervals of ¼ in., or crenulated, as in Fig. 3. By means of these crenulations it is possible to dispense with a gauge in setting out mortices and tenons; the long arm sliding along the wood, and a pencil being placed in the proper position, marks the tenon or mortice as truly, or more so, than a gauge. This may perhaps not be strictly roofing, but it comes under the same head, many roofs requiring a certain amount of framing in their construction.

On the opposite side to that shown in Figs. 2 and 3, the whole of the outer edge of the square is divided into inches, these being subdivided into twelfths, a very convenient division, as will be shown later on. The longer arm on this side of the square is

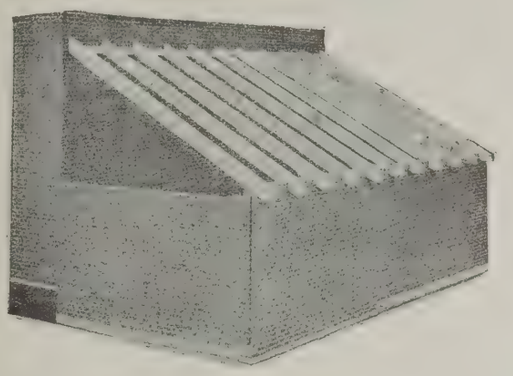


FIG. 4.

also divided into inches on the inside, these being subdivided into thirty-seconds; this is finer than usually desired for this purpose, but useful occasionally.

There are some other figures and scales on the square, the purpose of which will appear during the course of these articles, those already described being what really concerns the present subject. It may, however, be added that the steel squares are made dead true, both as regards the true right angle and the straightness of the arms. So true is the one belonging to the writer that he has used it for exact joinery work, as well as for the purpose it is meant for—carpentry.

Having thus cleared the way, how to frame an ordinary lean-to roof, all lengths and bevels being obtained by means of the square, from the plan only, will now be dealt with.

THE LEAN-TO ROOF.

The lean-to roof is the most simple of all roofs, and for this reason it is taken first in this series, its very simple character enabling us to show the principle of working apart from any complications in the roof itself. The complete roof is shown from two points of view in Figs. 4 and 5, and in section, as far as necessary for the present purpose, in Fig. 6, which will appear in the next instalment.

The width of the building is 8 ft., that is from the wall

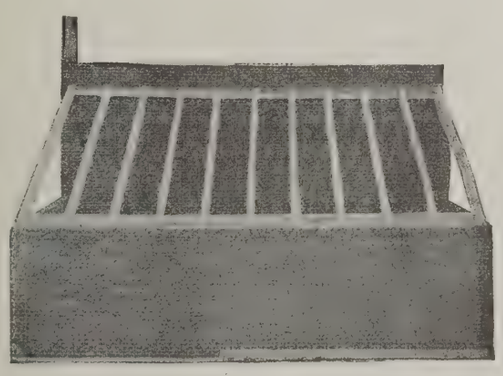

FIG. 5.

against which the tops of the rafters come to the outside of the wall plate, and the rise from the top of the wall plate to the top point of the rafters is 7 ft., this giving what is usually known as "tile" pitch. In passing, it is as well to say that a roof which has to be covered with tiles should not be made with less pitch than this, or there will be a risk of the wet finding its way in.

(To be continued.)

KEEPING THE MONEY AT HOME

Readers of THE BUILDER are deeply interested in keeping the dollar working, and keeping it working at home. At present, thousands of dollars are being sent away for "farms" or "lots" in distant states, when it should be kept at home. Money is "invested" in vacant property in new subdivisions and held for a rise in values when it should be spent in improving present property to produce an income.

No one thing helps a neighborhood more than to build a home in it. A large part, possibly one-third, goes out for labor right on the job. Fully as much more goes out for materials on which the local dealer makes his commission.

Every reader of THE BUILDER is interested in the building up, and every effort should be made to augment the movement "back to the homes." The architect can interest the owners in the newer and better methods of construction. The contractor is equally able to hunt up the people with a little money who are renting properties not entirely satisfactory, and others who have only to be urged a little to see the wisdom of having their own home now, instead of waiting until they have saved all the money necessary to pay cash for their home. When one considers that every house built means from $500 to $1,000 paid to mechanics in your own town, wouldn't it be well to make a little effort along that line?

In the building of homes of moderate cost, it is probable that building and loan associations take the lead. In the state of Illinois there are now nearly 600 such associations, with about $65,000,000 invested. One such association in twenty years has built 150 houses and is now lending nearly $3,000 every month to its members for building purposes. And yet there are carpenters and contractors, subscribers and readers of THE NATIONAL BUILDER who are not stockholders and are not keeping in touch with this means of increasing their business. Every builder should be interested in these associations, to know who anticipates buildings, and to be first on the ground to submit plans for their assistance and approval. The safest kind of business comes from it and you are keeping the money at home, where it was earned, and you are helping your friends and neighbors as well.

A DOLLAR DREAM

They wanted him to buy a farm
A thousand miles remote,
In regions that were full of charm,
The proud promoter wrote.
The more he thought and thought of it
The more he liked the scheme;
To think of it he used to sit—
And then he had a dream.

(Now, dreams are very foolish things
Undoubtedly, it's true—
Your brain puts on its fairy wings
And flies away from you;
And yet it seems that some of us
Our cash would never keep
Unless we learned a lesson, thus,
By falling fast asleep.)

He had a dream a dollar came,
With tears its features wet;
A dollar came and called his name
In anger and regret.
The coin was shedding silver tears
From out its silver eye.
He asked the reason for its fears;
The dollar made reply:

"They tell me you intend to send
Me many miles away,
They tell me you intend to spend
In speculation gay
The dollar that has been to you
A servant many years,
To send me to some region new—
And hence these silver tears.

"I've lived in this community
Almost as long as you;
I've been in ev'ry family,
I guess, but one or two—
But one or two who, sad to say,
Had such a scheme in mind
And sent their hard-earned cash away
Some other land to find.

"I am the dollar that was paid
To Johnson for his wheat,
That Johnson gave again in trade
To Murphy for his meat,
That Murphy gave to Smith, you see,
For furnishing a knife,
That Smith left at the grocery
For candy for his wife.

"The grocer gave me up to Jones,
Who runs the drygoods store,
And that the doctor set his bones
This Jones can thank me for.
The doctor paid me out for oats
To feed his dapple gray,
The feedman paid me on some notes
Fell due a certain day.

"The banker bought a book or two,
And so the thing went on—
Each night I had an owner new,
A new one at the dawn.
A welcome waited when I came,
A godspeed when I went,
In fact, a thousand ways the same
On errands I was sent.

"But now you say that I must go,
A wanderer to be,
Afar from all the friends I know
Who know and honor me.
I wonder that you dare to look
Me fairly in the face;
And in your empty pocketbook,
Oh, who will take my place?"

The speculator then awoke,
The dollar in his hand,
And softly to himself he spoke,
"At last I understand."
He gave it to the druggist's clerk
And bought a brush and comb—
He found a dollar does its work
The best right here at home.

Douglas Malloch,
in American Lumberman.

THE CONTRACTOR IS A SALESMAN

Probably it has not occurred to the contractor readers of THE NATIONAL BUILDER that they are salesmen. They are selling the materials and labor required to build a house.

We wonder if in talking with these clients they consider enough the need of salesmanship in securing their contracts. There is apt to be too much fear of losing a contract, and the anxiety prevents them from getting the right price for their job.

Just stop for a moment and consider the position of the man who builds. He is right from the "start off," at the mercy of the contractor. If you are a reliable contractor; have a reputation to keep, and have property or money to back it up, you ought to be able to get a better price than another contractor who has nothing. It is good salesmanship if you can show these points of advantage to the builder and receive his contract at a good figure.

A merchant comes to you for business, you have bought goods from him in the past and were not satisfied with the treatment received, you turn him down, and go to his competitor across the street and pay a better price. Just why do you do it? Simply because you found it pays.

Let us say you now have a chance to secure a contract to build a fine residence if you meet the other man's price. This other man is not reliable, and yet you are asked to take on a job simply because another has set a price. Good salesmanship talk here would bring you this job at your own figures. It is not necessary to run down your competitor. The thing to do is to praise your own work. Show him the buildings you have erected. Refer him to the people for whom you have done work.

LEAVES FROM A STUDENT'S NOTE BOOK. No. 1

BY GEO. METSON

Brief particulars of the three metals, cast iron, wrought iron and steel are as follows:

(1) Cast iron contains from 2 to 6 per cent of carbon; it is brittle, crystalline on fracture and cannot be forged or welded. Its safe resistances to tension, compression and shear are 1½ tons, 7 tons and 1 ton respectively. Its weight can be taken as 37½ pounds per superficial foot of 1 inch thickness.

All castings should have their internal angles well rounded, as when cooling, the crystals set at right angles to the enclosing lines of section, so that square angles would cause fracture at their junction. In a lesser degree external angles should also be rounded.

All changes of sections should be made gradually, as a sudden increase in the thickness of metal would, owing to the necessarily unequal rates of cooling, cause cracking.

Cast iron for joists is practically superseded in construction by mild steel, but cast iron for columns or pillars is employed on account of its high resistance to compression, and also, because where required an architectural finish is obtainable by means of mouldings, caps, etc., though it must be remembered that mouldings are a source of weakness to a casting. If ornamental caps and bases are required, they should be added as an extra casting and be fixed to the column afterwards.

There is a risk of flaws and cracks in cast iron columns. The flaw may occur in one of the lugs, cast on for joining up, etc., to the grave detriment of the joint and the column as a whole, for which reason steel for stanchions is now more often employed.

It is as necessary to protect cast iron columns from fire as it is with steel staunchions. The incased steel work would bend, twist and even give way, at comparatively low temperatures, while though the cast iron column might crack, it would continue to support its load, unless melting temperature was obtained.

Rough tests for cast iron are as follows:

(1) Strike the edges lightly with a hammer. If pieces fly off, it is too hard.

(2) If the hammer indents the metal, it is too soft.

(3) If it can be cut with a knife at places it contains too much carbon.

(4) If a milled or machined joint shows irregularity; some parts showing humps above the general surface, the metal has probably been badly mixed.

(5) If the casting shows surface lines of indentation, it has been run into the moulds too cold.

(6) The casting may contain holes on the surface filled with sand, etc., which may be proved by striking the metal, when the sand may be displaced.

(7) Lastly, check the dimensions. If necessary, a hole may be bored in a column shaft to ascertain the thickness of the metal.

(2) Wrought iron contains not more than ¼ of 1 per cent of carbon; it is tough, ductile, fibrous, forgable, weldable. Its safe resistance to tension, compression and shear are 5, 4 and 4 tons respectively. Its weight can be taken at 40½ pounds per superficial foot of 1 inch thickness. It can be used for rolled sections, tie rods, bars, bolts, rivets, etc., and can at high temperature be pressed into moulds.

In the trade there are two classes of materials; namely, "merchant bar" and "best bar," the latter being used for constructural purposes, being tougher and more easily worked than the merchant bar.

Each of these two classes are again subdivided, viz, "single," "double" or "treble," according to the number of times the metal has been through the processes of piling and rolling.

For constructional purposes, mild steel has largely taken the place of wrought iron.

(3) Steel is made by adding carbon to wrought iron, or by extracting carbon from cast iron, and according to the percentage of carbon it contains, so it can be welded or cast. Mild steel may contain up to ½ of 1 per cent of carbon and can be forged and welded. It is softer and yet tougher than wrought iron. Cast steel is much stronger than cast iron.

One noticeable property of steel is that it obtains a higher degree of elasticity than other metals, and another that it retains its magnetic power having once become magnetized, longer than iron, but is slower than iron in becoming magnetic.

If sulphur is present in excessive quantities, it causes the steel to be difficult to weld, becoming brittle when at red heat. This is known as red shortness. If phosphorus is in excessive quantities, the metal becomes brittle when cold. This is known as cold shortness, and such metal is of no commercial use.

Mild steel is now extensively used for constructional work, as roofs, bridges, floors, stanchions, etc. Its safe resistance to tension, compression and shear are 6½, 6½ and 5 tons respectively.

Cast steel is used for tool making.

It is sometimes difficult to distinguish between wrought iron and steel, so the following brief items may be useful in this direction.

(a) Plunge the metal in doubt when red hot, suddenly into cold water; if it becomes hardened, it is steel, if it remains unhardened, it is wrought iron.

(b) Steel will show a finer grain on a cut than wrought iron.

(c) A drop of diluted vitric acid will show a darker stain on a piece of bright steel than on a piece of bright wrought iron.

(d) The steel will emit a clearer ring than wrought iron when struck with a piece of hard wood; the metal to be tested being suspended.

The following points require looking to in construction:

(a) Steel should be free from laminations which are caused by the ingot from which the metal is rolled containing honeycombs.

(b) The dimensions should be correct with proper camber and rivets at proper pitch, and the riveting properly extended. That countersunk rivets are provided where required.

(c) The metal should be tested for tensile resistance at some experimental works.

WATERPROOF CONCRETE PAINTS

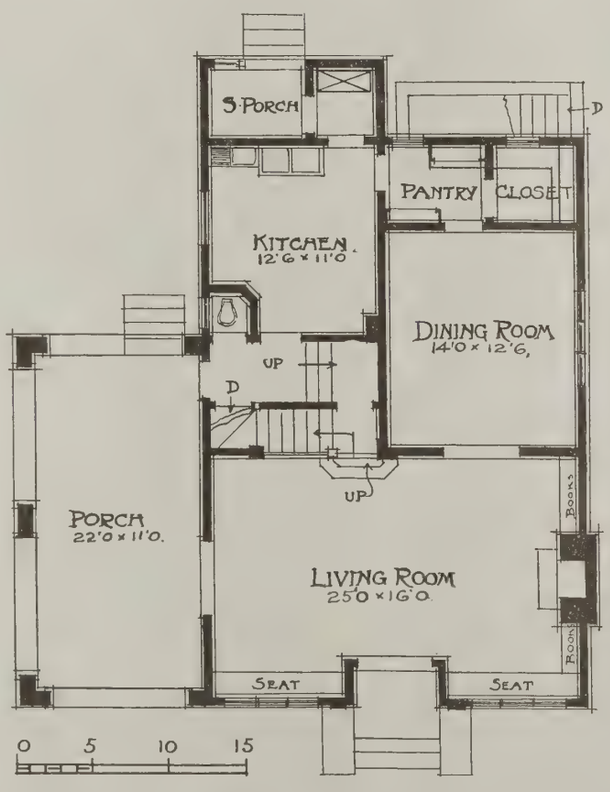
THE committee on treatment of concrete surfaces of the National Association of Cement Users, has investigated a number of the so-called waterproof concrete paints and finds that they are much more efficient than colorless solutions.

These paints may be divided into two classes: First, those which give white, or light tints or other colors pleasing to the eye and of a decorative nature; and, second, those which employ compounds of tar and asphalt which are necessarily black or nearly so, and are, therefore, seldom used on exposed surfaces.

The presence of a finely-divided pigment serves to seal up the small pores in the surface of the concrete, leaving less work to be done by the vehicle.

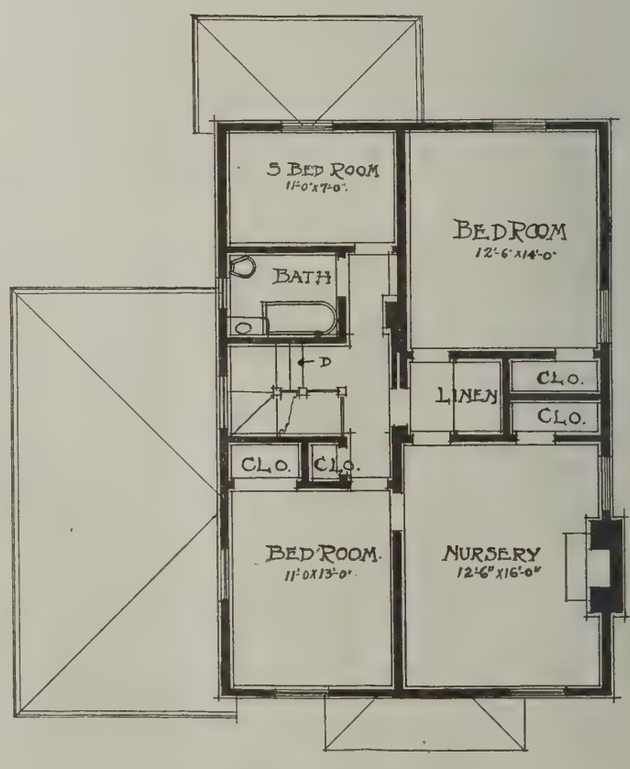
In most cases the proportion of pigment used is small, and by using a cement color but little change in the surface appearance of the concrete need be made, unless desired, while on the other hand, almost any shade or color may be obtained. In this way the waterproof-coating is made more serviceable and at the same time ornamental.

All these treatments are applied with a brush in the same manner as paint and are probably as durable on concrete as paint is on wood.



Linseed oil paints should not be applied directly to new concrete or to any concrete which has not been long exposed to the weather. The free lime in concrete not thoroughly weathered out on the surface by exposure to the elements will saponify the oil, destroying its adhesive power and its life, and the paint will soon scale off. After concrete has been exposed for a long time to the elements, linseed oil paint may be used with greater safety. It is difficult, however, to determine when the concrete is sufficiently free from lime to render it safe for the application of linseed oil paints, and it is therefore safer to avoid their use directly on concrete.

There are preliminary applications which may be given to concrete which renders it harmless to linseed oil paints. The best known, and perhaps the most thoroughly proven treatment of this kind, is that devised by Charles Macnichol, of Washington, D. C., and published in the transactions of the American Society for Testing Material for 1910. It consists in giving the concrete, after it has been thoroughly set, a priming coat of a solution of zinc sulphate, eight pounds to a gallon of water. This is applied with a brush, and after it is dry ordinary linseed oil paints may safety be applied over it.—*American Roofer.*



RESIDENCE AT HACKENSACK, N. J.

MANN & MAC NEILLE, ARCHITECTS.

FIRST FLOOR PLAN.

SECOND FLOOR PLAN.

A RESIDENCE AT HACKENSACK, N. J.

On a slight elevation overlooking the beautiful Hackensack Valley, the architects selected the shingled side house as best harmonizing with the surroundings. As will be seen the shingles are the old fashioned hand-split shingles one inch thick at the butt and exposed twelve inches to the weather. The enclosed porch can easily count for an extra room summer or winter.

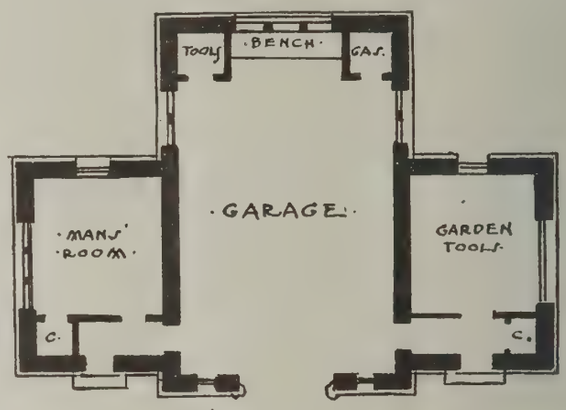
PLANNING A PRIVATE GARAGE*

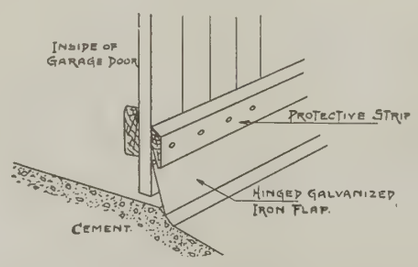
By. HERBERT L. TOWLE

Now let us consider the floor space in figures. To do anything of consequence around a car a width of ten feet is necessary, and an additional 2 feet is often useful. According to the length of the car, the minimum fore and aft length of a small garage must be 18 to 20 feet, and may be a little more for very long cars. This gives room to work around both ends, after allowing for headlights, folded Cape cart hoods, etc., and it gives a little leeway to avoid breaking the lamps when one drives in. If there are two cars abreast, the required width will be about 18 feet. If, however, the cars are to be washed in position, about 4 feet additional is needed to avoid splashing one car when the other is being washed.



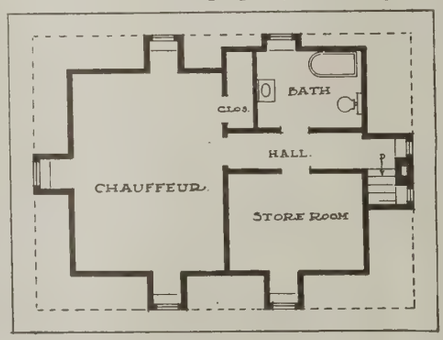
BY ALBERT WINSLOW COBB, SPRINGFIELD, MASS.

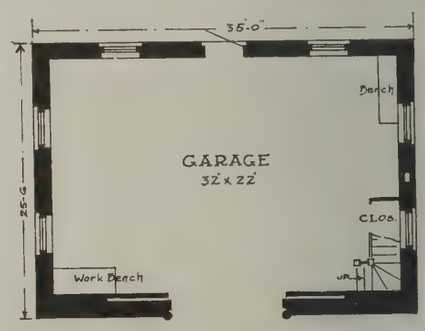
The bench should be 2½ to 3 feet wide, and from 6 feet upward in length, depending on the number of cars and the amount of work expected. Lockers, oil cans, etc., may be disposed in corners, but the gasoline pump and the washing hose should be near the door. An overhead trolley and chain hoist are useful. One end of the trolley should be over the motor, and the other near the bench. The machine tools, if any, should be near the bench, and they and the bench should have ample light.



If the body is to be staged at one side for overhauling or painting, about 5 feet will need to be added to the length of the garage from front to back, or 3 feet to its width.

From these considerations we see that the minimum space required simply to house a runabout and provide bench room is about 14x20 feet outside. Even this is crowded; it allows no room for machine tools, none for swinging a sledge, and none for staging the body. It serves the requirements of the average owner who is satisfied to let the repair shop do most of the overhauling. For a touring car from 2 to 4 or 5 feet should be added to the length, and for two cars side by side the width should not be less than 20 feet.





BY FRED. B. O'CONNOR, ALBANY, NEW YORK.

The above dimensions make no provision for heating, a subject which will be taken up later. Meanwhile we may remark that the heater should in all cases be partitioned off wholly from the room in which the cars are stored, and should be entered by a separate outside door, to avoid any possibility of explosive gasoline vapor reaching the fire. In the one-car garage a satisfactory arrangement is found by locating the heater at one side, with the shop space, as it may be called, beyond. It is even possible to run a curtain to screen the bench and tools from splashing when the car is washed indoors. A heater of some sort, it may be remarked, is essential for winter use in the latitude of Philadelphia and Chicago, as it is difficult to start an engine when the mercury sinks to 45 degrees, and it is physically impossible to do much work on the car at a lower temperature.

POWER MACHINES FOR THE WORKSHOP

BY GEORGE E. WALSH

THE carpenter beginning in a small way may be at first content with such hand tools as he has always had, and possibly one or two foot-power machines; but as his business grows, and he finds it possible to enlarge his capacity by taking larger jobs he begins to figure on the equipment of his shop with some of the simpler power machines. It is true that mills perform so much of the work today that formerly the carpenter did entirely by hand that the necessity for equipping the ordinary carpenter shop with expensive machines may not appear so urgent to some as to others; but if one is to do efficient work of a varied character a well equipped shop is the key to success. The carpenter who can take, and do, all sorts of jobs is more than likely to get the bulk of the best trade in any locality.

When we jump from hand and foot power woodworking machines to those operated by steam, gas or electricity, the question of what sort of power should be adopted is the first to cause worry. In a general way it was impossible for the carpenter to equip his shop with steam power unless it was run as a mill too, for the expense of installation and operation was too great. It has only been in recent years that gas and electricity have come in as a factor in the situation. For the small shop the question is reduced to the choice of electricity or gas. Steam is out of the question where the work is intermittent.

As to elecricity for shop operation of machines, it is largely a question of cost of current. If electric current can be obtained at very small cost, which is possible in many parts of the country where hydro-electric power is developed on a large scale from waterfalls, electricity is an efficient power for shop work. In using this power one pays only for what he uses, and there are no losses when the motor is shut down. Thus if one wishes to saw up a lot of lumber of certain lengths, he can turn on the current and start the machines going. When the job is finished the current is shut off and expenses cease.

If the shop is equipped with only one machine such as a table saw a single motor direct connected to the machine or belt-connected will suffice. This motor must have sufficient capacity to drive the saw at full load. If two machines are installed, another motor can be direct connected to this the same as the first, but when three or more are put up the question is whether it will pay better to have a separate motor for each machine or all the machines driven by a single large motor by shaft or belt. We know that when power is transmitted by belt and shaft there is a loss amounting all the way from 10 to 20 per cent. That is, this power is wasted in driving the shaft and in the friction of slipping belts and pulleys. This waste must be taken into calculation in group driving. On the other hand the initial cost of installation may be less than to purchase an individual motor for each machine.

In theory and practice it may be said individual motor drive is the most satisfactory where the tools and machines are operated only occasionally, but in a shop where the operation of most of the machines is uniformly steady the group-driven system by shaft and pulley is the most efficient. The first cost of a small motor is proportionately greater than a larger one, and where a separate motor is installed for each woodworking machine there must be a duplication of power. Thus if we have four motors of two horse-power each in a shop to drive four machines, we have a total of eight horse-power. Now a single motor of five or six horse-power would undoubtedly be sufficient to drive all four of the machines if they were connected up by shaft and belt. The total aggregate of horse-power of a shop equipped with separate motors is therefore greater than in another using the group system of drive.

But there are other compensations. If anything happens to the shaft or motor in the group system all the machines are put out of commission. Where separate motors are employed a single motor may get out of order, and only one machine is stopped. The group system of drive is clumsier than the separate motor method, for there must be constant connecting and disconnecting of shaft and pulleys, and this takes time and often a good deal of labor to adjust things. Belts will slip and get out of order, and even shafts have a habit of breaking down. If a sudden hurry job comes in which calls for the operation of a single machine, it may be that all the others are connected up and these must be disconnected before work can begin. With the separate motor a touch of a button or turn of a switch handle throws the current on, and the work begins, and when through the motor is stopped just as quickly.

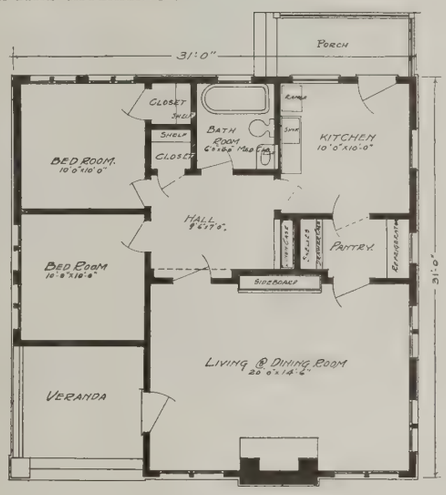
If there is no special price for current, the average carpenter will find the gasoline engine cheaper than electricity. There has been a good deal of prejudice in the past in equipping woodworking shops with gas power. Some have an idea that the danger from explosions is great, and that, with shavings around, the gas engine threatens the whole shop. Without doubt the gas engine is just as safe as any other form of power, and it is being generally adopted for all kinds of woodworking concerns. But it must be properly installed and operated. The adaptation of the gas engine to the carpenter's shop has reached a point where it is handy, safe and efficient. Saw outfits, for instance, are already made with the gas engine attached to the table in such a way sawdust and shavings can fall on any of the exposed parts of the engine without causing fire or clogging. The dangerous parts of the engine are inclosed in such a way that a child could run one without causing a fire of any kind.

The gas engine is the most economical power producer we have, and it is equally adaptable to automobiles, boats, airships, and shops and factories. The gas engine has the same advantage that the electric motor offers. That is, when work stops the cost of power generation also ceases. There is no waste of energy while waiting for the next job. This economy of power must be considered, for in the long run it amounts to a good deal.

The gas engine is also used in much the same manner as the electric motor, either for individual drive or in connection with shafting or pulleys. For a single woodworking machine a small gas engine of one or two horse-power will answer all purpose, but in a shop with several machines the extra cost of power to drive all of them will be very small. A five or six horse-power engine will usually drive all the machines that a carpenter shop will have. It is very seldom that all of the machines will be operated at the same time. If we figure upon an engine capable of operating three-fourths of the machines at once we will therefore select one of about nine horse-power for a shop that is really a twelve horse-power one. In general factory practice this is not considered good practice. The horse-power needed is figured for the full capacity of the shop when all machines are in operation at once, and this would be the correct thing in a woodworking shop where the running of all the machines at once is frequent. But the small shop rarely needs all of its machines at the same time, and it is perfectly safe to figure on the smaller horse-power capacity to save initial cost.

The shafting, pulleys and belting should all be made as light as possible to do the work, for the loss of driving these must be considered. Extra heavy shafting and belts make for losses. The shafting should be run in a straight line, and the gas engine should, if possible, be placed in the middle instead of at one end. Thus in a shop of four machines, two should be on either side of the engine. It is much easier to turn a shaft with the load evenly divided on either side of the center than with all the load on one end. The extension of the shafting can then be made in either direction to accommodate more machines as they are added.

A short shaft for only a few machines requires no coupling and cut-off arrangements. It can easily be turned without loss of much power. The machines not in use are disconnected by throwing off the belts. But when the shaft gets long it pays to have a cut-off arrangement so that a part of the shaft can be left idle. This cut-off system is very simply arranged when the engine is placed in the middle of the line of shafting. The drive belt from the engine is connected to a short length of shafting or a jack shaft with a coupling on each end, attaching it to the line shafting in each direction. With these couplings and convenient levers half the line shafting can be cut off and the other half operated. The whole shafting can be thrown into operation by a touch of the lever and all the machines started up as needed. The extra cost of this coupling equipment will be more than paid for in a short time by the saving of the power and of time in operation. A well equipped shop that works efficiently and economically pays better in the end than another clumsily arranged, and the owner soon realizes that it is economy to spend a little more at the beginning and have everything in first-class shape.



PERGOLAS IN THE WIDE STREET ADD TO THE PARK-LIKE APPEARANCE.

A CALIFORNIA BUNGALOW

Among the reasons for the charm and attractiveness of the bungalow are the possibilities for pleasing surroundings. It takes very little foliage to give a nestling, home-like effect, and when an entire district is laid out with the idea of harmonious surroundings, a little effort creates wonderful results. In the illustration shown herewith, the four-room bungalow is situated in a little park, and, although the buildings are rather close together the open spaces front and back overcome the appearance of crowding.

For the interior we have a very convenient arrangement, the large hall opening into all the rooms. No parlor would indicate the occupation of the whole house all the time, unless indeed the surroundings are so pleasant that one is tempted to stay outside most of the time. In a land of continual sunshine, where this bungalow is built, a parlor is really an unnecessary room, for one would not occupy it during meal time, nor would it be probably used for a bed room. Where the habit of sleeping out of doors, is strong, it is possible to effectually screen the porch and thus practically secure another room.

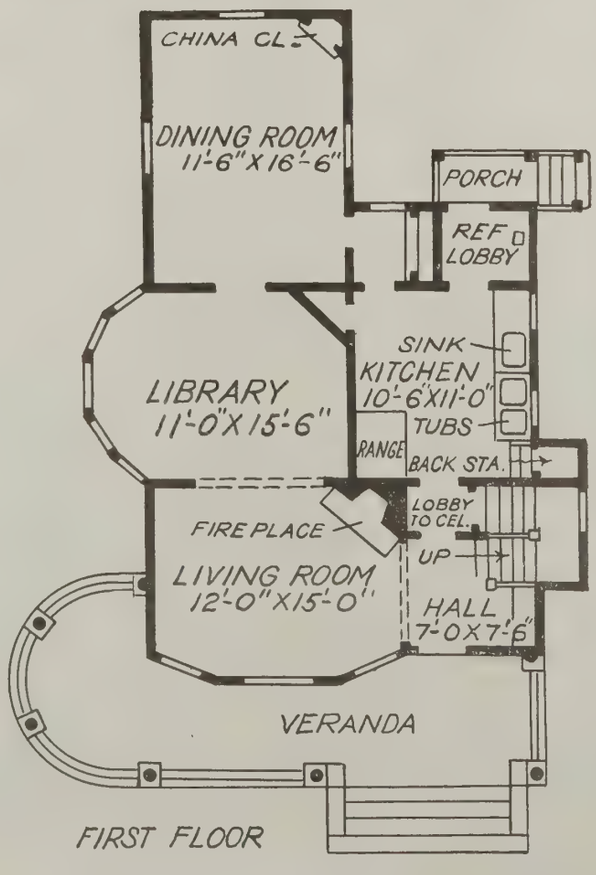
FLOOR PLAN.

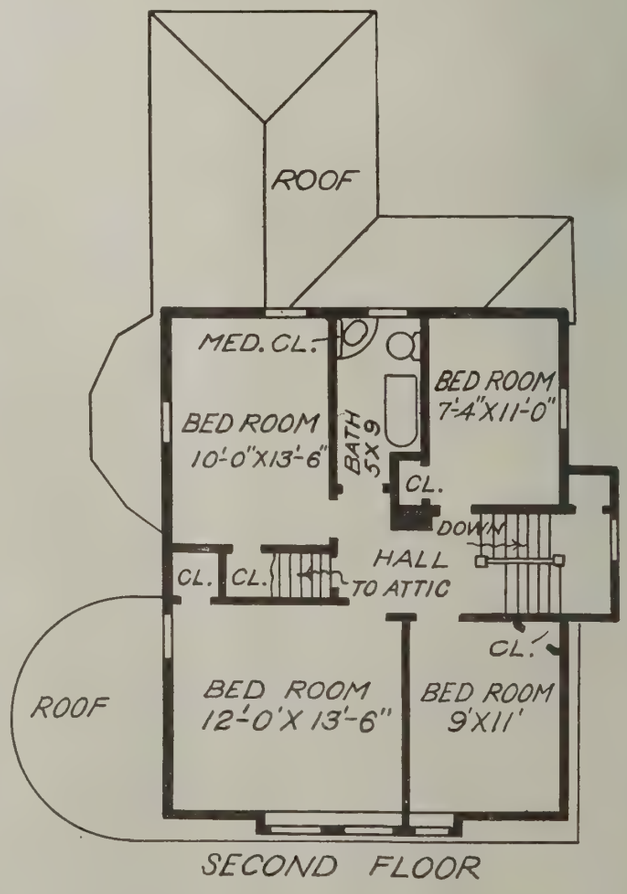
PLACED WELL BACK FROM THE CURB, THE BUILDING IS EASILY ORNAMENTED BY PLANTS AND SHRUBBERY.

A SUBURBAN HOME

By LOUIS BAURY

THIS is one of the attractive suburban homes, situated within forty-five minutes of a large eastern city, which, while possessing all the essentials and characteristics of a $10,000 house, was built under contract for a trifle less than $5,000. The house, which has been occupied more than a year, is the work of William A. Lambert, a New York architect, who makes a specialty of houses that are both cheap and artistic. The low, picturesque treatment of the exterior is in pleasing harmony with the surroundings, the shingles, stained dark brown on the sides, with moss-green roof and white trimmings, combining to make a strikingly effective exterior.





The little piazza, cuddled down in the southwest corner of the house, is large enough to serve as a playground for the children, or accommodate fairly good sized tea parties during the warm summer months, when eating out of doors is one of the pleasures of the country dweller.

The arrangement of the interior is eminently practical and convenient. One enters a cozy little hall, containing a staircase of oak, over which a stained art window sheds a soft, pleasant light. A long, low mission seat and railings, and newel posts, match the stairs. The family now occupying this house by simply piling the seat with cushions and throwing a rug across the floor space has given the hall such a comfortable, cheery atmosphere that it serves as a delightful lounging room.

The living room, library, and dining room are on the southern side and, by opening into one another, give an enlarged floor space of very pleasing appearance. In the living room is a tasteful fireplace and a parquet floor, two things which go far towards establishing an effective ensemble. In the library the cheery, homelike

atmosphere is preserved chiefly by means of a large bay window, through which the sun pours generously nearly all day and in the warmth of which all kinds of flowers thrive and blossom. A touch of dignity is lent by the columns between this and the living room.

The prevailing air of cheeriness extends into the dining-room, a large oblong place jutting out in the rear of the house. Windows on three sides admit a constant flood of light and sun; in one corner an attractive china closet is built, and the room is bordered by plate racks.

All three of these rooms, as well as the halls, are tinted, and the dining room is finished in burlap down as far as the plate rail. The ceilings are tinted in such manner as to harmonize with the woodwork, and, in the living room and library, heavy, old-fashioned beams stretching across the ceilings, give a rich, stately touch, which is not often encountered in houses costing as little as $5,000.

The remainder of the ground floor is given up to the kitchen and butler's pantry. The former is provided with a large cooking range, a white enamel sink and a spacious closet. The butler's pantry is compact and convenient, being fitted with the customary dresser and drawers.

One of the particular features of this floor is a platform connecting the main stairway with the back stairs, and forming what is known as "combination stairs," one of the most serviceable of devices in saving time and steps. The cellar is finished in concrete and has a complete steam heating apparatus, as well as coal and wood bins and storage space.

In the second story, there are four bed rooms, each large, airy, light and in every way sanitary; the two on the front of the house built out over the roof, thereby gaining a largely increased floor area. Each of these rooms have good sized closets and a splendidly arranged medicine chest is built into the corner of one of them.

The bath, sandwiched in between the two rear bed rooms, is of good size and has excellent ventilation through a large window. It is equipped with exposed plumbing, white porcelain-iron bath tub, an oval wash bowl of the same material, and an improved syphon closet. The woodwork is finished in white enamel, blending well with the fixtures. The floor is tiled, and the sides covered with metile, while the walls above are painted.

From this floor a staircase, uniform with that below, leads to the attic, which is floored and has one finished room, designed for the servant.

The windows on the first and second stories and in the attic are all fitted with hardwood wire screens, planned to stand more than the average amount of wear and tear from rough weather. The front and rear doors also have detachable screens, as have the cellar windows. Shades are provided for all windows, and the house is heated throughout, and lighted by both gas and electricity.

The exterior woodwork is painted two coats and the shingles then stained. Inside the woodwork in all the main rooms is stained, in mission finish, in dull brown, greens, and Flemish. Throughout are parquet floors, the whole combining to make a house of as much solidity as artistic effectiveness.

The detailed cost of this house was:

Carpenter work	$2,850
Masonry	925
Plumbing	325
Heating	300
Painting and decorating	210
Window screens	65
Gas and electric fixtures	85
Parquet floors	150
Electric wiring	65
Total	$4,975

A careful study of the accompanying plans will show how a few clever devices of the architect have caused a saving of nearly a thousand dollars, without detracting from the desirability of the house. Perhaps the most important is the extension of the second story over the piazza roof, thereby gaining a large amount of additional space at a saving of over two hundred dollars.

Another economical move was making one chimney serve for furnace, laundry, kitchen range, and fireplace. Lastly, the heavy beams in the library, which look so imposing and expensive, are nothing more than a part of the beaded floor of the rooms above. By allowing these beams to hang down, many square feet of plastering and a proportionate amount of outlay are saved.

A HUSTLING CONTRACTOR

By W. WEBB

BEING alert to the changes that are going on in our industry becomes one of the essentials that every carpenter, contractor or jobber should keep before him. If he understands and appreciates the fact that there is wisdom in doing things well, then he must appreciate the importance of making prompt deliveries, and of doing his work with alacrity. How to do this properly is one of the most important considerations that should be heeded by the man who has progressive ideas as to the conduct of his business.

He understands that when there is a contract to be let that unless he has been among the first in the field he will stand little show of gaining the reward of his labors. Once secured, however, the obligation of carrying out the tenets of the same demand more attention, and the greatest care. This includes all the details that are to become a part of the contract. One of these is in having the materials "on the job" with promptness. Upon this sometimes depends the future success of his undertaking. Let it become known that he is dilatory about this one matter, and the news will soon spread far and wide. It will be a source of annoyance and loss of business to him in all his future undertakings.

How is he to obviate this difficulty? By having his own team, is the most natural suggestion to make. Does he understand that the method of handling much of the modern day business is done along entirely different lines? With all due respect to the time honored horse, it is safe to assert that the day of this animal, for many purposes, is passing. Now the contractor who wishes to do hurry up work; to get material on the job with due haste, and who has no longer to depend upon the horse drawn vehicle, does so with his power wagon.

Does he understand that the motor wagon is replacing the horse drawn vehicle? That depends upon the way in which he views the trend of modern events. That depends upon whether he is a man of progressive ideas, or whether he is one who is still content to operate along the old ways of a generation age.

Time is now a factor that must be reckoned with in doing much of our work. It is as much the man who can do things quickly as can do them well that is in demand. If you operate a motor wagon in connection with your industry, the fact is soon made known to many, and the effect is at one like electrification. That means progress, and there is a certain prospect accorded the man who is a hustler.

The time, labor, cost and inconvenience saved by the contractor who uses a motor vehicle in his business is not to be compared with the opposite inconveniences that are met with by the man who still adheres to the old time methods. This is a fact that is worthy of consideration. The argument is made by some that the cost of operating a wagon of this type is too great to make it an advantageous mode of conducting that part of his business. How is the comparison when the cost of a horse, or a team is calculated? The motor wagon is only costly when in operation. The horse is still eating and still demands attention even after the work hours are past.

These are simply a few facts that have come to mind in the course of some rambles about cities and towns, and from observation of the methods that are pursued by the various contractors. It is always a notable fact that the man who is most prosperous is the man who takes the lead in doing things that count for the most in the end. It is observable that the man who is alive to the present day needs in the construction industry is the man who counts time as a factor that must be reckoned with, and who does not hesitate to adopt all means that will minimize and reduce such waste as is possible with means that are to be had if they are but sought out.

A BUILDER'S COURSE IN ARCHITECTURAL DRAWING.

RALPH F. WINDOES.

(Continued from May.)

DEVELOPMENT OF SURFACES.

THE process of unfolding the surface of an object, such as the coverings for the surfaces of solids, etc., and laying it out on a flat plane is called development of surfaces. It will be found a very interesting subject and one with which the student should become thoroughly familiar. It is suggested as a means of more thoroughly understanding the subject that you develop and cut out some of these surfaces from cardboard so they can be folded up to form the exact model in which they are intended to represent.

Next we will develop the covering for this prism. Draw the bottom line of the prism over to the right and on it lay off 6 spaces, *qr, etc.*, equal to one side of the prism, or *op*. Draw vertical lines up from these points and project points *a, b, c* and *d* over until they intersect these lines as shown in *s, t, u, v, etc.* By connecting these points we have developed the covering for the side of the prism. The bottom is the same as the bottom of the prism, so it is drawn in as shown. The top is the same as that developed at A and for convenience is drawn in at the highest point of the covering. Here we have *vw* equal to *kn*. With *v* as center and *vw* as radius

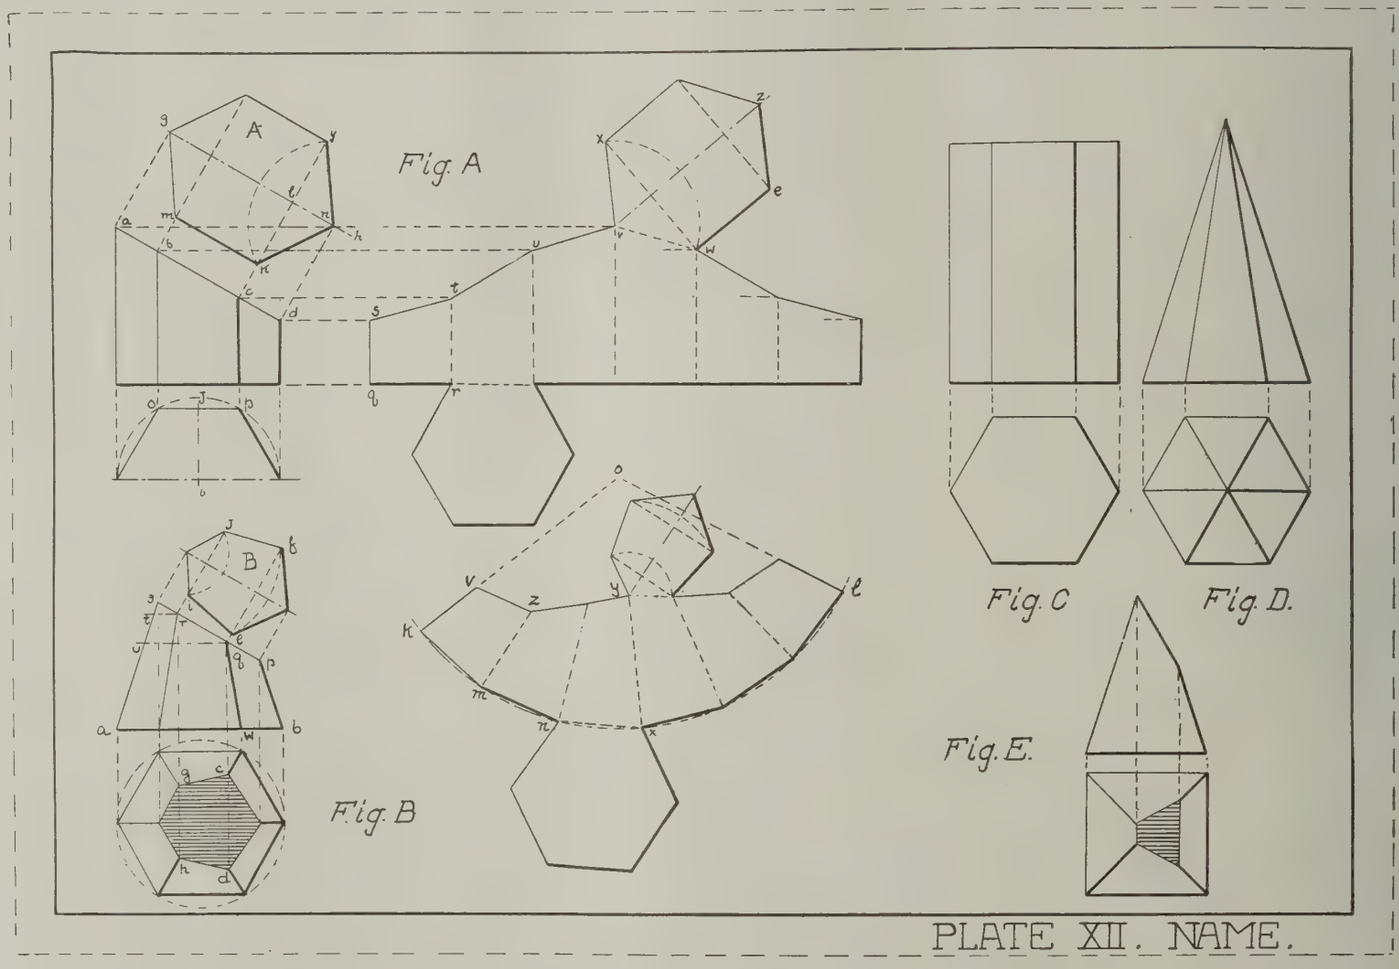


PLATE XII.

DEVELOPMENT OF SURFACES.

In Fig. A we have the hexagonal prism whose top is cut off at an angle of 30 degrees to the horizontal. First draw the half-plan and the side elevation, remembering that each side is equal to the radius of the circumscribed arc. Cut the top off at an angle of 30 degrees as shown in the drawing. It stands to reason that the sloping top of the prism will not be the same in shape as the bottom, so we must find its exact shape in order to determine the shape of the covering we wish to put upon it. We will view it at right angles to its surface and the result is shown at A. To draw it correctly, project points *a, b, c* and *d* at right angles to *ad*. Draw the center line *gh* parallel to *ef*. Set *kl* off equal to *ij* and draw side *km* parallel to *gh*. With *n* as center and radius equal to *nk*, draw the arc as shown and complete the view by connecting the points located.

draw the arc as shown. Make *wx* equal to *ky* and draw *vx*. Bisect angle *wvx* by the center line which should be parallel to *wx* if properly done. Make *we* equal to *mk*, and parallel to the center line. Draw *vz* equal to *ng* and finish the development.

In Fig. B we have the frustrum of a hexagonal pyramid, the top being cut off at an angle of 30 degrees to the horizontal. Construct the prism as shown, starting with the plan view. To draw this, first construct the hexagon and then draw diagonals from opposite corners of it. Project the point where they cross in the center up to form the apex of the pyramid. Project the corners of the plan up to the base line *ab* and connect these points with the apex. This forms the pyramid. With the 30 degrees triangle cut it off as shown and project the points of intersection with the sides down to the plan where they will cut the diagonals. When these points are joined we will have the plan view as shown. The section lines are put on for the sake of clearness. The sloping top at B

is developed in the same way as the one at A, remembering that *cd* is equal to *ef* and *gh* equal to *ij*.

To draw the development, first draw the arc *kl* with a radius equal to the length of a true side of the pyramid as from *a* up to the apex. Bear in mind that this side would be longer than from *w* up to the apex as you are looking at the latter as it slants away from you. Next lay off *km, mn,* etc., equal to a side of the base of the pyramid. Connect these points with each other and with point *o*. Continue by laying *kv* off equal to *bp* and *wx* equal to *as*. As we said before, *wg* is not viewed in its true length, but if it is projected horizontally over to *as,* a side that is shown in its true length, we obtain it exactly as it should be in the line *au*. Then lay *mz* off equal to *au*. Do the same with point *r* and *at* gives its true length. Lay this off on the development and repeat all of these lengths on the other side of *xy*. Connect these points. The covering for the top is put on in the same way as the covering for the prism and the bottom is self-evident.

On another sheet, or two, develop the surfaces for the solids shown in Figs. C, D, and E. Fig. C is a hexagonal prism, Fig. D a hexagonal pyramid, and Fig. E the frustrum of a square pyramid. No difficulty should be experienced in the working out of these problems as they are much more easily solved than the ones already explained.

In Fig. B is given a hollow cylinder whose top is cut off at an angle of 30 degrees, and the surface development of the same. Draw the plan and the side elevation and divide the plan up the same as was done in the case of the cone. Project points *1, 2, 3, etc.,* up until they cut the top of the cylinder as at *a, b, c, etc.* Draw the base line of the development *de,* and on it lay off the twelve equal spaces. Draw the verticals up through these points and project *a, b, c, etc.,* over until they cut these verticals. This locates points *f, g, h, etc.* Through these points draw a neat irregular curve, as shown.

Fig. C presents a problem. Here we have a cylinder, its top being cut off at an angle of 45 degrees. It is required to draw its development. As seen at A, a perpendicular view of the face takes the form of an ellipse. The method of locating the points shown on its edge, through which the curve is drawn, is left for the student to solve with the help of the numbers given. Notice that *ab* is perpendicular to the sloping top, and *cd* perpendicular to *ab*. The covering is developed in the same way as the one in Fig. B, but with the addition of the top and bottom as this cylinder is solid.

Fig. D is the drawing of a three-piece elbow. Only the side elevation is here given. The development of it is required. Draw the indefinite center line *ab* at an angle of 45 degrees, and draw *cd*

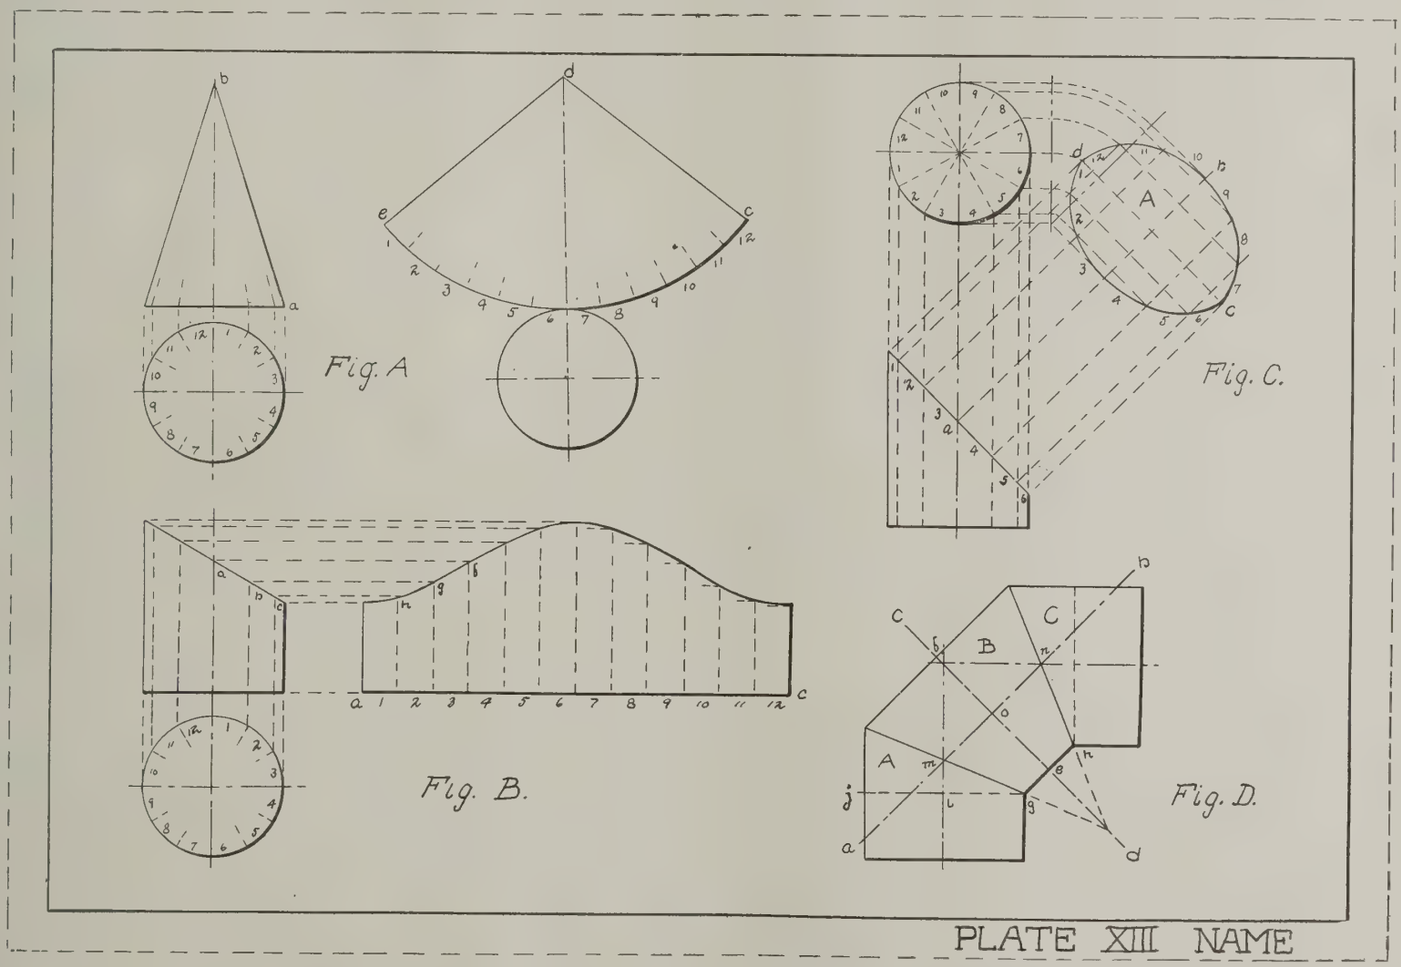

PLATE XIII.

DEVELOPMENT OF SURFACES.

On this plate we have a few problems in the development of cylindrical surfaces. There is a great similarity between these and those on Plate XII, but extreme care should be used in working them out.

In Fig. A we have a cone and its development. First draw the plan and elevation, making it any height desired. Next divide the circumference of the plan into any number of equal parts, in this case we have taken twelve. Next set the compass point at *a* and with a radius equal to *ab,* the slant height of the cone, draw an arc. Connect one end, as *e,* with *d* and with the dividers lay off the twelve spaces as shown, each equal to one of the divisions on the circle. It is easily seen that the more spaces the circle is divided into the shorter the arc between the points becomes, hence the nearer *ce* would approach to exactness. Connect *c* with *d* and finish the development by putting on the circular bottom.

at right angles to it. Lay off from *o, oe* and *of,* each equal to half the diameter of the pipe. Supposing *gh,* the length of the shortest element of the center piece known, draw through *e* a line parallel to *ab,* and set off the distances *ge* and *eh,* each equal to half this length. From *g* draw the horizontal *gj* and set *ig* and *ij* off equal to *eo*. Draw the verticals through *g* and *j* and through *f* draw a line parallel to *ab*. This gives us the intersection of the bottom piece with the center piece. The top piece is drawn in exactly the same way, working from the center lines of each member.

The development of this pipe is easily worked out if sufficient care and forethought is exercised in so doing. Pieces A and C are alike and are developed in the same way as the piece in Fig. B. Piece B is similar but it has the curve on the top and bottom. In developing it, it must be separated from the main body so that *cd* is a horizontal line.

(To be continued.)

OUR READERS' PAGES

[The Editor does not hold himself responsible for the opinion of correspondents. Short, crisp letters will be appreciated. To insure publication, the name and address of the writer must accompany the communication, not necessarily for publication. Sketches of work or methods will receive our earnest attention. These columns are open to our readers at all times without cnarge, and any questions or experiences will be given proper space.—Editor.]

ANSWERS

ESTIMATING BY THE CUBIC FOOT.

From "Estimator," Yonkers, N. Y.

In reply to J. L., Staples, Minn.

In estimating the cost of building by the cubic foot method, the entire cost is comparative only; the contractor should make it a point never to use this method when he has time to take off the quantities in detail.

As a means of checking an estimate, it is an excellent method, but there are so many details entering into the construction of a building that it requires considerable experience to know what unit price to put upon the several structures.

As you will note in the July number, the price for cubic feet for cottages varies from 3c to 14c, all depending upon the detail of finish and construction.

In each of the prices quoted, you will note a difference in the construction and finish, which causes a difference in the prices.

As a general rule, a building is figured complete, including basement, walls, floors, roof, interior finish, painting, etc. The construction and finish being what is ordinarily settled in a building of that particular character. In taking the measurements for estimating by the cubic foot, it is the practice to measure about one foot below the basement floor and up to a point two-thirds of the distance from the eaves to the roof or to the ridge for the height, and to take the average for ordinary size on the ground for the other two dimensions, disregarding balconies, porches, chimneys, etc., unless they are of such a character and size as to make it necessary to include them.

If you will check up the cubic feet in the buildings you have erected and compare with the cost, you can easily find just what these buildings have cost per cubic foot, and this will give you a good basis for comparison for future work.

You can also figure the cubic contents of the various plans which have appeared from time to time in THE NATIONAL BUILDER, compared with the estimated cost, which will also give you an excellent basis for calculation.

STEEL SQUARES.

From Wm. P. T. Trenton, N. J.

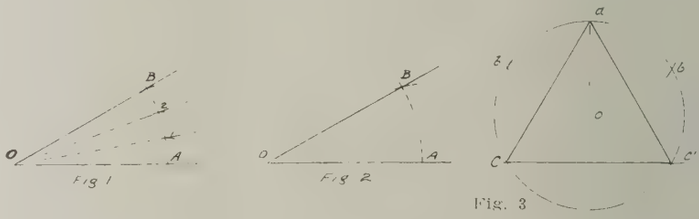
Young framer, of Seattle, Wash., has evidently gotton hold of one of the real good, old framing squares of fifty years ago. The eagle square was made in Troy, N. Y., and was the standard square for many years, and I might say, that away back in the fifties it was every young carpenter's ambition to own a good eagle square, and in those early days, when dollars were as difficult to get as gold eagles are now, it was quite an event to purchase a reliable steel square. The old square was strong, true and very reliable, but, of course, the figuring and rules on it were antiquated, and difficult to understand. The Sargent square, No. 100, is very much superior in makeup, figuring, finishing and tables, and is very much better for present use than the good old Eagle. The square made by the Nichols Company of Ottumwa, Iowa, is another good square, and possesses many features that add to its value. One feature is that the corners of the square, including the ends of blade and tongue, are hardened, as hard as steel can be made, a process that prevents wear on the corners. This firm is also manufacturing a square in which the tongue can readily be disconnected from the blade, thus enabling the tool to be stowed away in a very small space. The square also carries a table on its surface, for getting the cuts, bevels and lengths for braces, rafters and hips.

LUMBER SYMBOLS.

From T. N. B., Chicago, Ill.

I reply to H. A. B., Cleveland, Ohio, with regard to lumber signs, the expression 18,803 8 in. No. 122 siding means, 18,803 square feet of No. 1 double V siding, 8 inches wide.

The expressions, 12/10, etc., are to indicate the numbers and lengths in which the material is to come. That is twelve pieces ten feet long, etc.



The expression S1S1E means that the lumber is surfaced or planed on one side and one edge, the other two surfaces being just as they came from the saw.

DIVIDING ANGLES.

From "Draftsman," Chicago, Ill.

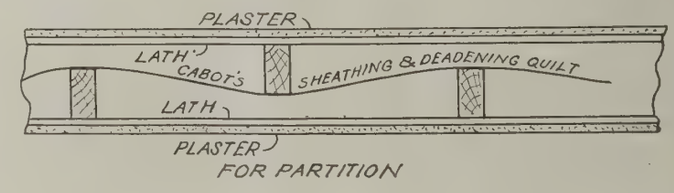
In answer to W. G. L., New Haven, Conn.

There are several mechanical methods of dividing angles into several parts, but the simplest and quickest method is to describe an arc through the angle, using as long a radius as possible. With the dividers, space off the arc into the required number of parts and draw lines from the center "A" to the subdivisions.

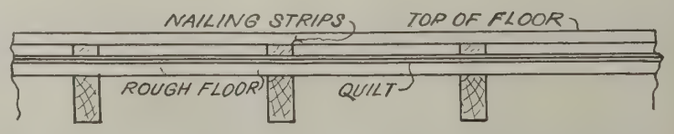
FIGS. 1 AND 2.

To lay off a given angle, draw an arc, using the same radius as before. With the dividers or a compass, measure off the arc of the given angle and lay off this distance on the second arc.

To inscribe an equilateral triangle in a circle. In the given circle, Fig. 3, draw a line *o a* from the center to the circumference. Lay off this distance twice from *a* to *b* and *c*, and from *a* to *b'* and *c'*. Through the points thus found, *c* and *c'*, draw the lines to form the triangles.



DEADENING FLOORS.



From "Builder," Chicago, Ill.

In reply to Fred, Flint, Mich.

The question of sound-proofing is rather difficult, as the sound may be carried through the air, or through the boarding of the floors and partitions. The method suggested by the manufacturers of Cabot's sheathing quilt is shown below. It will be noted that no part of the partition extends through, except at the top and bottom. This method should take care of any sound except that which originates on the floor. The same "Quilt" may be used between double floors, laying the quilt directly on the lower floor, and nailing the top flooring to strips which are simply laid on the quilt, care being taken that the flooring nails are not long enough to go through the strip into the lower floor.

"Linofelt," made by the Union Fibre Company, is a prepared deadener for the same purpose. Get the catalogues of these two firms and you will see the best way to use them.

QUESTIONS

HOSPITAL.

From a "Committee Man," Edmonton, Northwest.

I am one of a committee appointed to make inquiries, and arrange if possible for the building of a general hospital, and would like to get such information as will be of use to the committee in determining the "lay-out" of the building—which is to be of brick—and requirements necessary. It is intended to design the building so that it will serve a city of say 50,000 people and so arranged that at present it may serve 10,000 or 15,000 people, and can be added to as necessity requires. Any information or suggestions on the subject will be gratefully received.

MEASURING A CIRCULAR ARC.

From "Young Bricklayer," Dayton, Ohio.

Will some kind reader explain in this department, how to find the length of a circular arc, and oblige a new reader?

SIX, EIGHT AND TEN.

From "Country Contractor," Prairie Farm, Francis, Sask.

I have heard and read concerning a rule for squaring the foundation of a building by the use of a ten-foot pole from which the figures 6, 8 and 10 are used only. Please describe how this is done?

DAMP-PROOF WALL.

From "Plasterer," South Bend, Ind.

I wish to make a brick wall in a measure "damp-proof." There is less than fifty yards of wall surface, but at times, after rain in the spring and fall, it shows signs of dampness. Can I cure it by plastering it with cement, and if so, how will I proceed to get the best results?

TO DRAW AN ELLIPSE.

J. E. L., Shenandoah, Iowa.

Permit me to ask through your columns how to draw an ellipse, major axis 4½ inches in length, the minor axis 3 inches in length (with just a rule or square and dividers), the shortest and quickest way.

CUTS FOR DIFFERENT PITCHES.

From H. H., Emporia, Kans.

It would be valuable information to me if some one would explain how to get the different cuts and the lengths of the valley and cripple rafters; where, for instance, a third-pitch roof is joined to a half-pitch roof.

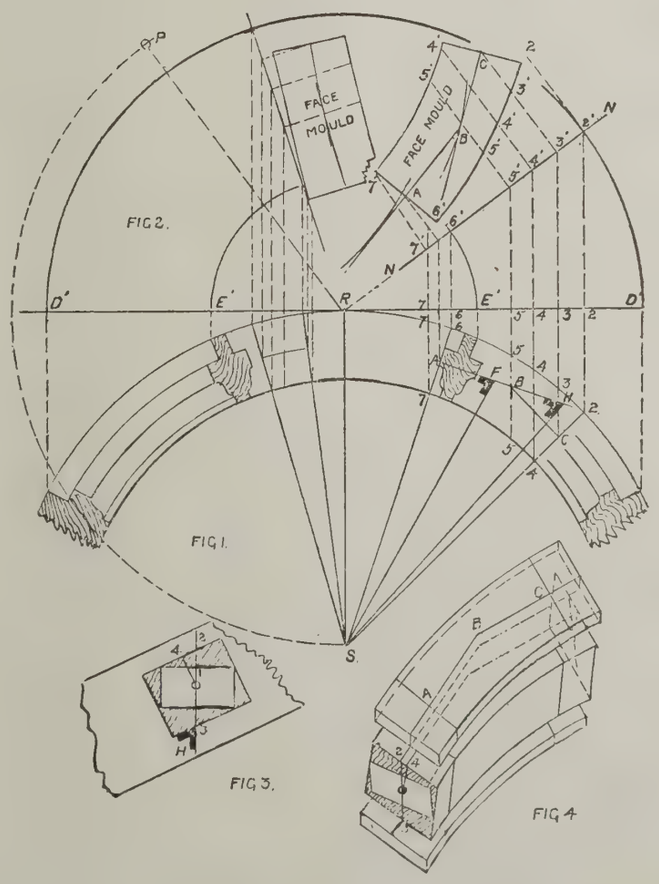
How do you get the cut for the foot of the common rafter of, say, a third-pitch roof running parallel with a half-pitch roof, and resting on the sheeting of the half-pitch roof? I want to know how to get these cuts with the steel square without making a drawing.

BUILDING A BALANCED RAILWAY.

From G. S., Clayquot, B. C.

I have to build a track to haul up provisions from the beach up on high land. The track will have about 2 inch rise a foot run. It will be a double track and one car filled with water. Shall on the down track pull up a load on the other. Now I would like the editor, or any other reader of THE NATIONAL BUILDER, who has had experience, to give his opinion if the scheme will work and if so, would like to have a plan how to arrange the drum and brake—in short, would like to have some information about it.

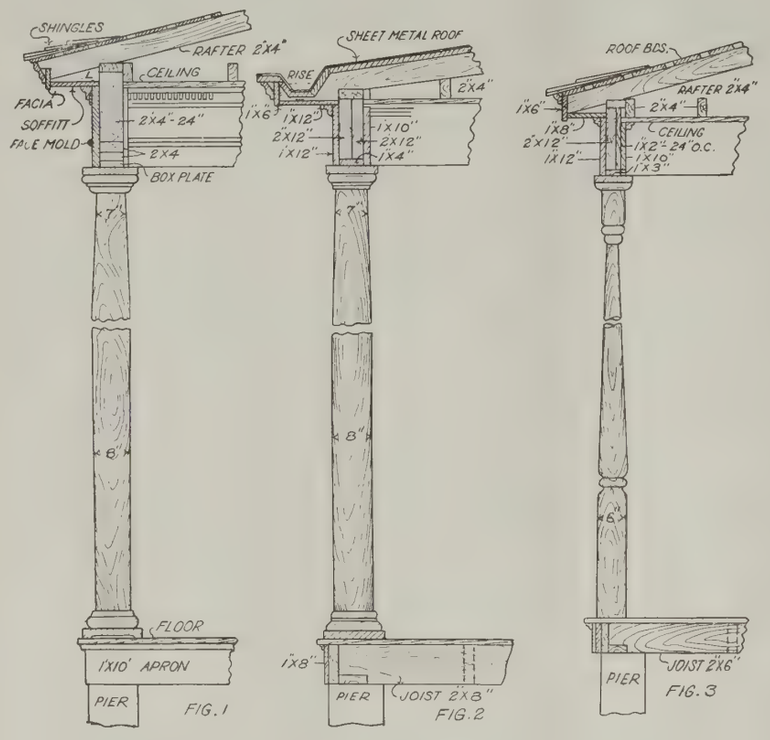
PLANS FOR GYMNASIUM.



From J. W. A., Birmingham, Ala.

What is the usual floor space of a college gymnasium, where can I get any plans, especially floor plans for a gymnasium suitable for a college?

RADIAL BARS FOR CIRCULAR SASH



THE accompanying sketch shows a method of getting out the radial bars for a sash circle on plan and semi-circle in elevation.

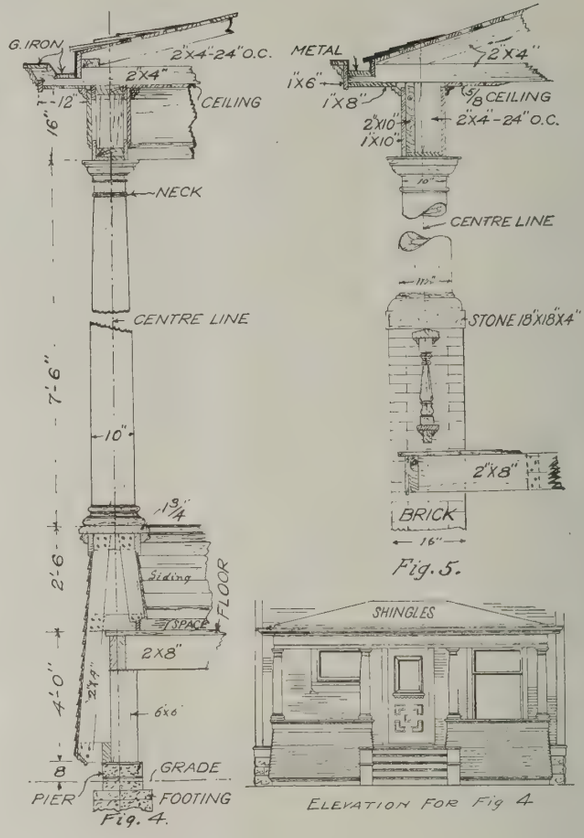


Fig. 1 shows the plan, and Fig. 2 the elevation above the springing. The semi-circle, D'D', Fig. 2, represents the rebate for glass, also the depth of the sinking of moulding on inside of sash. The shoulders on top end of each radial bar would fit against this. The semi-circle, E'E', will be the shoulders on bottom end of radial bars. N N represents the centre of lower bars. Make 2'2', 3'3'c, 4'4', 5'5', B5', etc., Fig. 2, equal corresponding figures, Fig. 1. Join A B and B C for tangents. Trace the outside of mould through 2', 3', 4', 5', 6', and the inside through 4', 5', 7'. Draw the lower joint through A square to A B, and the upper joint through c square to B C. A bevel for each joint will be required. From R draw the line R P square to N N, and make R P, Fig. 2, equal R S, Fig. 1. With P as centre, and for radius strike an arc to just touch the tangent, C B, on face-mould; with this distance in the compasses place one foot at S, Fig. 1, and cut either of the tangents on plan as shown at H. Then the required bevel is contained in the angle made by the lines AHS. Repeat the process for the joint at A, only touch the tangent A P on face-mould instead of C B. This bevel is shown at F. To find the thickness of stuff draw the bevel H across a piece of board (that being the sharpest of the two bevels), draw a square section of the bar square to this line, as shown by the unshaded part, Fig. 3; the shaded part shows the thickness of stuff. Leave a bit of stuff on each end of face-mould past A and C to allow for tenons. Cut the bars out to pattern of face-mould square through the plank, and mark the tangents on to it. Square the tangents across each joint as shown by 0 4, Fig. 3. Pass the respective bevels through the centre, o, as shown by 2, 3, Fig. 3. Draw lines on face of stuff from where the bevels cut the edge of joints parallel to tangents. The tangents on face-mould would be kept to these lines when applied for working inside and outside of bars. The application of face-mould on both sides of stuff is seen at Fig. 4. It is not necessary to describe the other bars, as they would only be a repetition.

FIVE STYLES OF PORCH DETAILS

BY STEVENSON

Porch building brings into play a great variation of details; when the carpenter is supplied with complete working plans and details for the job all these should be shown clearly.

There are, however, many cases where the carpenter is called upon to work out his own details and it is with this thought in mind that the writer offers the five sketches herewith shown, to aid the carpenter in this work.

I am not dealing with the platform and joist to any extent, as these are all pretty much the same in all cases and are fairly well understood by all carpenters.

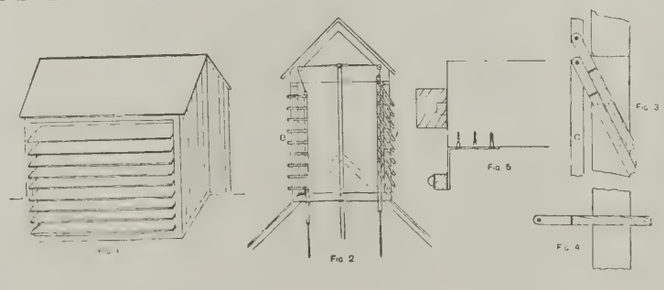
What I wish to deal with mainly is the building of the box plates and cornice. Fig. 1 shows the frame for the box plate made with double 2"x4" at the bottom, and single 2"x4" on the top for plate, with 2"x4" struts cut at about 24" centers, the 7/8" facing boards being well nailed to this frame-work. L shows the bracket nailed to the rafter tail to form the lookout to receive the soffitt of the cornice; this is a good, suitable box-plate for a span up to 12'. Fig. 2 is two 2"x12", spiked together and cased in with 7/8" boards. This method should be followed for spans of 12' or over. Note the manner of framing for the gutter.

Figures 3, 4 and 5 are other methods that make very good plates for spans up to 12'. It must be remembered, however, that if the porch is to be a double decker, where a greater weight than the roof will be upon it, it must be made still stronger.

Figure 4 calls into play a little different detail at the base in order to provide for the splay in the siding as noted by the elevation, which the details clearly explain. Fig. 5 shows a brick pier above the top of handrail showing the detail of the rails and balusters.

A RIDGE VENTILATOR

BY F. W. LOASBY



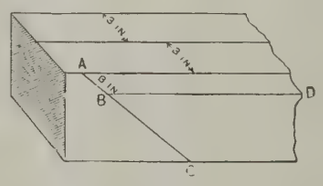


FIG. 1 is an elevation of a suitable roof ventilator, the dimensions being ruled by the size of the building to be ventilated. The framework is of 4½-in. by 3-in. pine posts, 6-in. by 3-in. sills, 4½-in. by 3-in. beads, the ends being boarded on the outside. The roof is similarly covered, and both are covered with zinc or other suitable roof covering. Fig. 2 is a section showing the louvres closed, giving permanent ventilation; on the opposite side they are open to the full extent. When the louvres are required to exclude ventilation, they are framed as seen in Fig. 3. Fig. 4 shows a louvre open to full; Figs. 3 and 4 are in section; Fig. 5 is a plan of the same louvre. On the edge at the end of the inside of the louvre boards are fixed angle iron brackets; the projecting ends are drilled to receive a small bolt by which each is secured to the operating rod C; this rod is of hardwood. To work the louvres a cord is attached to each end, and on the inside top end rail are fixed pulleys to receive the cords. In the center is fixed a double sheave lazy pulley, over which the two cords are passed, so that both sets of louvres are controlled over the same pulley. The position of the louvres being determined, the cords are secured to a cleat hook fixed at a convenient height from the floor; a cord fixed to the lower end of operating rod enables the louvres to be easily opened.

BACKING HIP RAFTERS

The enclosed sketch represents a stick 6x8, and the line A the foot of the rafter. Take half the face of the stick, which in this intsance is 3 inches, and mark from toe of rafter 3 inches along the line A. By this you have the point from which to draw the line B. This rule is correct every time.

STEEL SQUARE PROBLEMS

By J. E. NUITT

Being an interested and appreciative reader of the BUILDER and interested in steel square problems, as discussed therein, especially as applying to hip roofs, etc., I herewith forward some problems relative thereto, and hope some of your readers may gather some light on what is generally a puzzle to the "prentice" hand, or to that vast army who "just look it up." Abe Lincoln said that a "man's legs should be long enough to reach the ground," and should as sound principles admit of universal application, a hip rafter must be long enough to reach the common rafters at the right place, and cut in the right way to fit; and if the learner can be induced to consider one end of a hip roof as consisting of four triangles whose bases are the plates of the building and whose apex is the point where they join the peak of the common rafters, and comprehend the fact that the length or shortness of the triangle is determined entirely by the pitch of the common rafter, he will have the key to the situation.

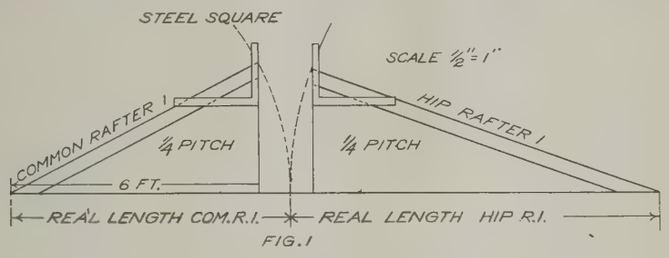

FIG. 1

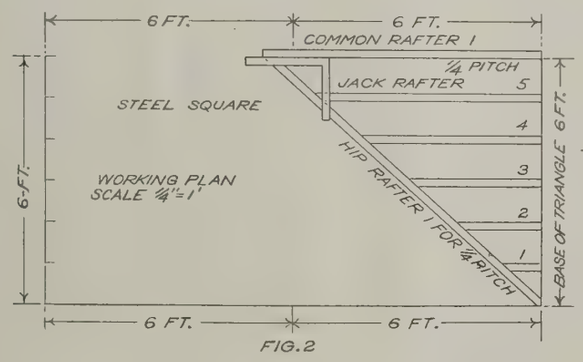

FIG. 2

I think it will be plain to anyone by the figures herewith shown, how to get the side cuts for both hips and jacks; also their lengths. They are just the same. This is to say, of course, that the side cut for the one-third pitch, for instance, is the same for that series of hips and jacks, while the plumb and bottom cuts for the jacks are the same as for the common rafters for one-third pitch.

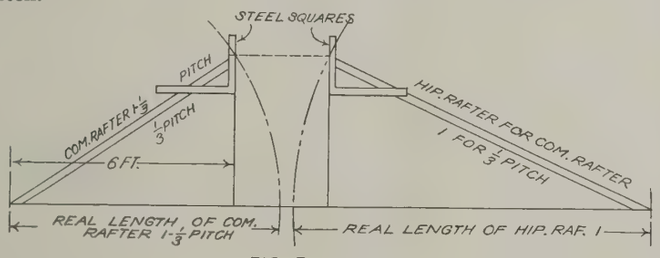

FIG. 3

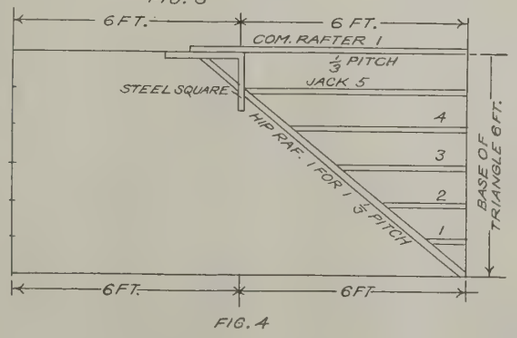

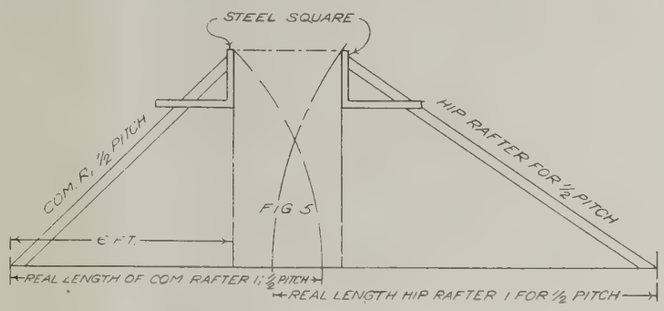

FIG. 4

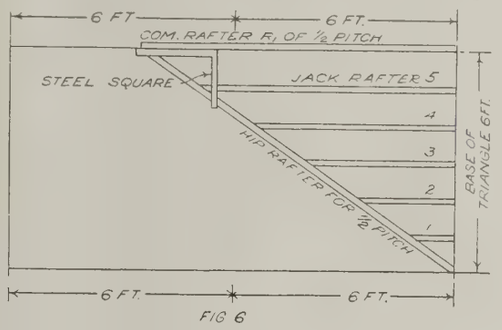
Now, there are few practical facts about the square, which are very useful to know in connection with these problems. For instance, the cut for a quarter pitch is 6x12 for the common rafters. Now, as 12 is to the common rafter, so is 17 to the hip rafter, so long as the hip is square or regular. So then, as the cut for the common rafters for one-quarter pitch is 6x12, then the cut for the hip rafter is 6x17. Again, as the cut for one-third pitch is 8x12 for common rafters, the hip cut for same would be 8x17. Still again, as the cut for one-half pitch is, of course, 12x12, the hip cut for same is 12x17. But, Bulwer says, "We must first conjecture before we can experiment, and experiment before we can discover," so the novice will learn more by going to work than by any other means. None the less, others who have gone before have discovered many valuable facts and things which the beginner in any line will do well to avail himself of.



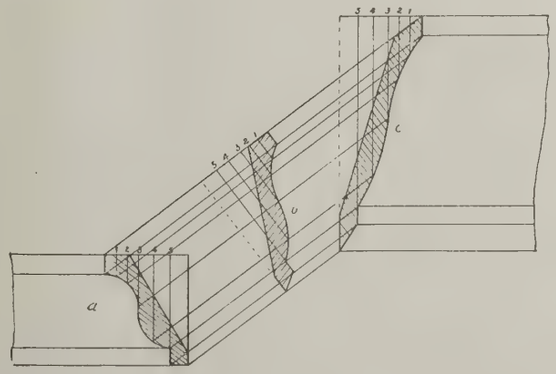


FIG 6

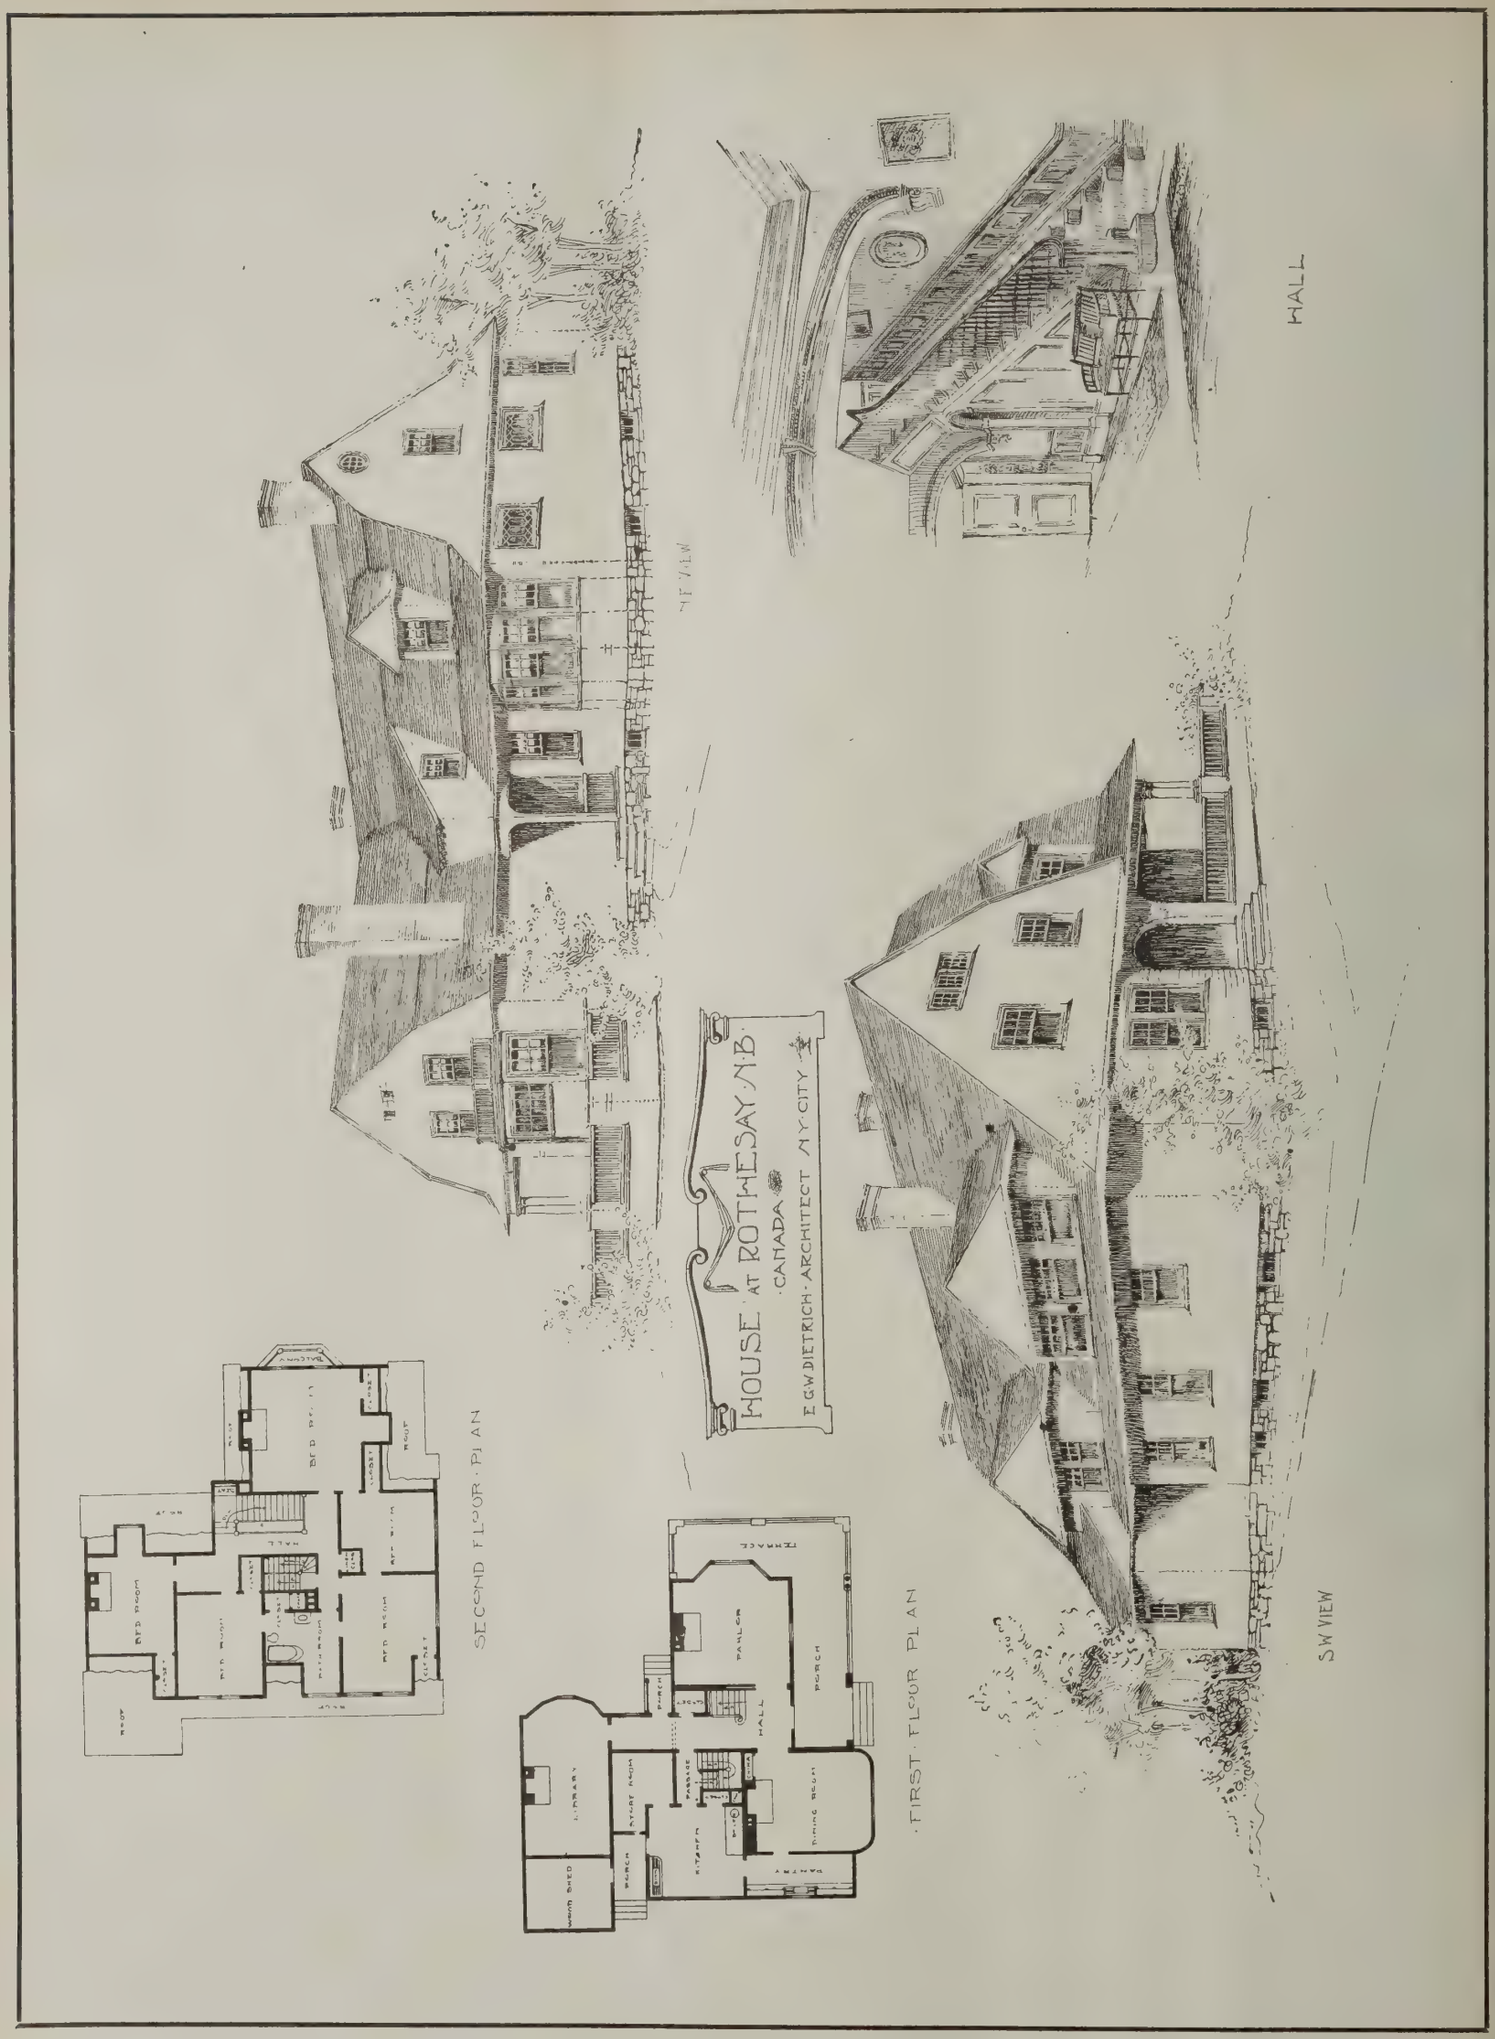

The steel square is shown in the "working plan" as laid across top of hip to give side cut for hip. Of course, this is also side cut for jacks. The horizontal view can hardly need explanation. The cuts can just as well be got with bevel rules, and for practical working, two bevel rules—one set for the side and the other for plumb cuts—are very handy, and I have found it very convenient to bolt two or more boards together upon which to draw the working plan, generally 1 in. to foot measure, and work the length for every piece. It is obviously necessary to draw only one-fourth of roof or one triangle, as shown in sketch.

If the operator will draw his plan and scale correctly, he will have but little measuring to do, and as for the square, he can lay that aside when he goes to frame his stuff, provided he has made his plan and can refer to it at a glance.

DEVELOPMENT OF A CIRCULAR MOLDING

Here is a bent sprung molding laid out to stand over the inside of a circle, and this time the development is made above the ceiling instead of below it. The reason for this is quite simple, although it is not always apparent at first thought. In the first example the top of the molding occupying the larger circle when in position must come on the long side of the blank, as shown at b o, while in the second case the top of the molding must necessarily conform to a smaller circle than the bottom and must be laid out on the shorter side of the blank, as shown at a b.

BOOK NOTICES

(Notice.—All books noticed in these columns may be obtained from this office at Publisher's prices. All postage or express prepaid. Money and address must accompany all orders.)

ALADDIN HOUSES.—"Direct from the forest to the home"—"Houses built in a day." An illustrated pamphlet published by the North American Construction Company, Bay City, Michigan.

This is a "lively" little pamphlet, showing some 150 plans, elevations, interiors, and detail illustrations of "knock-down" summer cottages and bungalows, varying in cost from $185.00 to $1,750.00. The prices named are for houses complete and ready to occupy, including all materials, painting and plastering. These prices are often less than the cost of the rough material.

MAPLE, BEECH AND BIRCH FLOORING.—Being the official maple flooring book containing concise and authentic information for architects and builders concerning the characteristics and uses of maple, beech and birch flooring. This is a handsomely gotten-up little brochure, well illustrated with colored pictures of various trees in their natural homes and conditions. It is published by The Maple Flooring Manufacturers' Association, 1308 Rector Building, Chicago.

CONCRETE REFERENCE BOOKS: Practical Silo Construction—Number 3 of the Series; being a treatise illustrating and explaining the simplest and easiest practical methods of constructing Silos of all types; with unpatented forms and molds. The data, information and working drawings given in this book should enable the concrete worker to successfully construct any of the most practical types of concrete Silos in use at the present time. 70 pp., limp cover, a score of practical illustrations, published by the Norman W. Henly Publishing Company, New York, N. Y., 122 Nassau St. Price, Postpaid, 50 cents.

The work is by A. A. Houghton, the well known writer on matters of cement and concrete.

This series of reference books are all terse and simple on the subjects which they discuss, and cannot fail of being mighty useful to all those who are in any way engaged in cement and concrete work of any kind, and who may be fortunate enough to own all, or one of them, as they are practical, up-to-date, and presented in simple and understandable English.

The series consist ot twelve numbers, two of which were noticed in these columns a few months ago. The numbers now issued, and before me as I write, are No. 1, Concrete Wall Forms; No. 2, Concrete Floors and Side-walks; No. 3, Practical Silo Construction; No. 4, Molding Concrete Chimneys, Slate Roof Tiles; No. 5, Molding and Curing Ornamental Concrete; No. 6, Concrete Monuments Mausoleums and Burial Vaults. The serials are all uniform in size, well illustrated, well printed on good paper, in good sized type; and will be sent to any address in the United States or Canada postpaid on receipt of price, either from the publisher's office, or from the office of this paper.

THE GYPSUM INDUSTRY.

[From Consul General Robert P. Skinner, Hamburg, Germany, together with data from advance chapters of United States Geological Survey publications.]

Pure gypsum is a hydrous lime sulphate having a chemical formula $CaSO_4.2H_2O$. Few deposits of rock gypsum large enough to be worked for plaster are, however, even approximately as pure as this. Gypsum, as excavated for a plaster plant, will usually carry varying and often high percentages of such impurities as clay, limestone, magnesian limestone, iron oxide, and silica. Where the material occurs in an earthy, granular condition, it is known as gypsite, and this form of the mineral may carry 10 to 20 per cent of impurities.

Process of Preparation.

Gypsum loses the chief part of its content of water when heated to 110° or 120° C., and is completely dried when the temperature is brought up to 170°. The burned gypsum, not entirely relieved of its water, hardens when mixed with water, the peculiarity which renders it so valuable. When the burning process is continued until less than 3 per cent water remains it is known as "dead-burned gypsum." All of the burning processes require a completely even heating of the material, especially if the pieces are large and of unequal size. When small quantities are being prepared they may be burned in iron ovens, after having been pulverized, this heating being continued until a metal plate held over the ovens no longer accumulates drops of water.

When large quantities are being prepared, the gypsum is burned in ovens in which the gases from the fire are prevented from coming into contact with the material. To obtain the finer products, the ovens are heated indirectly, or the necessary temperature is obtained with a wood fire, the ashes of which are removed, as in a bake oven, before the gypsum is put in place. Modern ovens are now on the market which provide for a convenient and economical handling of the raw material, which is manipulated in accordance with the above principles.

As it is much easier to crush dried gypsum than the natural rock, a process is used, where the manufacture of large quantities is concerned, which admits of the burning of pieces of considerable size. The pieces are first slightly heated and then crushed, and the powder subsequently reburned. By this method a quick-hardening material is obtained which is suitable for stucco work, plastering, or modeling processes. For the manufacture of the slow-hardening material, which is used for building purposes or laying pavements, the mineral is first heated to incandescence, after which it absorbs water very slowly, but after the expiration of a few weeks becomes very hard.

Production in the United States.

The quantity of gypsum mined in the United States in 1909 was 2,252,785 short tons, an increase of nearly 31 per cent over the production of 1908, which was 1,721,829 short tons, and an increase of more than 28 per cent over that of 1907, which was 1,751,748 short tons. The gypsum sold without calcining and used principally as land plaster and as an ingredient in Portland cement and in paint showed a large increase in quantity but a loss of about 11 cents per ton in value; but the material calcined for plaster showed both a large increase in quantity and an increase of 30 cents per ton in selling price at the mills. The total value of gypsum and gypsum products in 1909 was $5,906,738, as compared with $4,075,824, an increase of $1,830,914, or 44.9 per cent.

Exports and Imports of Gypsum in Germany.

The gypsum exported from Germany amounts to nine times the quantity imported. Of the imports, one-half is from France and consists of very special grades. The price realized on gypsum shipped into Germany will depend wholly upon the quality of the article offered.

THE MOST DIFFICULT BUILDING REQUIREMENTS TO MEET.

EVERY man that has been in the building and contracting business long, probably feels that he has been up against some pretty severe restrictions and specifications at times, and up against some requirements that were pretty hard to meet. Some have found it in connection with requirements for fireproofing, others have found it in the exact government specifications, some in one way, and some in another, but when it comes to a show-down, it is doubtful if any builder in the United States has ever been up against what is really the hardest requirements to meet in erecting a building. That may sound like drawing it pretty strong, but what would you say if you were required to put up a building proof against earthquakes, tornados, and fire?

That is what they have to contend with down in the Island of Martinique, where, it will be recalled by many, there were some disastrous earthquakes and volcanic eruptions a few years ago, and where there is ever recurrent disasters due to earthquakes, hurricanes, and volcanic eruptions. There has been trouble ever since the country was settled by the first French colony, and the one idea all the time has been to construct an edifice to withstand the hurricanes and earthquakes, and be as nearly fireproof as it can be made. They have tried a great many experiments down there, and now, according to a report from Consul Thomas R. Wallace, they have found the plan that is in pretty general use at the present day to be about the best thing along this line that it is practical to construct.

Here is how they do it: The buildings in the cities are mostly two stories with dormer windows in the attic, but no cellars. Wood frame construction is resorted to, that is, a sort of mill construction in which some fairly heavy framing is used, and it is very carefully and thoroughly braced and trussed. The corner posts are bolted to the sills and joists, with iron bars and rods, and virtually two sets of framing are put up for the lower floor. The spaces between the studdings on the first floor are filled in with stone and mortar, making a wall about 20 inches thick, which is faced on the inside with boards attached to a framework of wood. In other words, it is practically the same as if one should put up a very substantial false work to carry a concrete wall 20 or 24 inches thick, with the framework on the inside of the wall, and the boards making the outside and just leave it stand. Only, instead of regulation concrete, they seem to use merely stones and mortar to get weight and body, but they still want the wood and its bracing and bolting together to withstand the shock of earthquakes.

In other words, a stone or concrete or other hard material building, while it may stand hurricanes and be more nearly fireproof, it seems that it is more liable to damage through eruption and earthquakes than one in which there is a reinforcing frame of timber to hold it together.

The upper stories are constructed with what seems to be a double set of studding or extra heavy framing without any stone or mortar filling.

The walls are 10 or 12 inches thick and the studding is simply dressed and planed and not ceiled on the inside. There are iron bolts passing through the studding in the outer wall and big iron washers on the outside to hold the wall and the frame together firmly.

For the flooring inch stock is used generally in wide units dressed both sides and matched. The floor of the second story forming the ceiling of the lower story like the old pioneer houses in this country. The partitions are made of practically the same stock, but instead of extending clear up to the ceiling, they stop about 1½ feet short of it and the space is filled with an iron trellis to permit a free circulation of air.

There is very little window glass used, naturally, for hurricanes and earthquakes continually break it out. Doors and shutters are made with movable slats, of the type we know here as outside blinds, and often there are additional outside doors, like our stormdoors, to close up for security at night. It is the slats in the doors and shutters, however, that are depended upon during the day for both air and light.

The country houses are generally lighter in construction. They are made one story of frame surrounded by a veranda or porch with quite a lot of iron used for support and railings around the verandas.

Strange as it may seem, tiling is the general roofing material with them. It seems odd, too, where lumber enters so extensively into the building operations, for we generally associate tile with stone or brick buildings and wood shingles or other lighter material with the frame buildings.

Evidently, however, they need the fireproofing qualities of the tiling down there. Anyway, it is said that tiling is used more than any other roofing, but some slate and metal roofing and a few metal cornices may be seen.

BUILDING TRADES INTERESTS IN THE COURTS

A materialman has no lien for glass broken before any attempt to use it in the building, and the owner of the building cannot be held for the loss.—Pittsburg Plate Glass Co. v. Leary, v. 126 N. W. (S. D.) 271.

Under the provisions of the mechanics' lien law the "owner" of real estate on whose interest a mechanic's lien will attach is the person for whose immediate use and benefit the building, erection, or improvement is made.—Johnson v. Soliday, 126 N. W. (N. D.), 99.

While an employer may employ contractors to do the work which the law requires of him, he cannot delegate to them the exercise of that care which the law imposes upon him personally.—Winslow v. Commercial Building Co,, 126 N. W. (Iowa) 173.

A mechanic's lien will not attach to the interest of a vendor under an executory contract of sale whose vendee is in possession, and who makes improvements by erecting buildings on the real estate covered by such executory contract.—Johnson v. Soliday, 126 N. W. (N. D.) 99.

Where the obligation of a building contract survived the contractor and was binding on his estate, his surety in a bond conditioned on the performance of the contract was bound to the performance of the contract after the death of the contractor.—MacDonald v. O'Shea, 108 P. (Wash.) 496.

Where the employment of a superintendent for the construction of a building was necessary in view of the character and size of the building, the administrator of the contractor could employ a superintendent, and the surety of the contractor was liable therefor.—MacDonald v. O'Shea, 108 P. (Wash.) 436.

A building contract stipulating for the certificate of the architect as to whether breaches of contract have occurred, or whether payments are due under it, requires the party seeking damages for a breach embraced in the stipulation to allege and prove that a certificate was given.—Heidbrink v. Schaffner, 127 S. W. (Mo.) 418.

A contract for the erection of a building on sloping ground, higher in the front than in the rear, which stipulates that the foundation wall shall be four feet below the ground, is not complied with where the foundation in the rear is placed on the surface of the ground, and the contractor, by filling increases the level of the ground two feet above the bottom of the foundation.—Villhauer v. Gross, 122 N. Y. S. 520.

A building contract stipulating that the parties for themselves, their heirs, executors, administrators, and assigns agree to the performance thereof is binding on the administrator of the contractor; it not being contemplated that the building should be the product of the contractor's personal labor or skill either as a laborer, mechanic, or artist.—MacDonald v. O'Shea, 108 P. (Wash.) 436.

A surety on the bond of a building contractor, conditioned for the performance of the contract, stipulating that the contractor shall protect the property against liens, may pay lienable claims before the expiration of the time for filing the liens without waiting for the filing of the liens, and hold the contractor or his estate liable therefore.—MacDonald v. O'Shea, 108 P. (Wash.) 436.

Where the vendee in an executory contract for the purchase of real estate is in possession and erects buildings thereon, in which the vendor has no interest except by reason of his holding the legal title as security for the purchase price, and when such vendor is not a party to the purchase of the material or the construction of the improvements, the question of his knowledge of or consent to the furnishing of material or the making of the improvements is immaterial.—Johnson v. Soliday, 126 N. W. (N. D.) 99.

A contractor, in a building contract which stipulated that the owner on obtaining a certificate of the architect might terminate the contract and complete the work, and that the expense incurred by the owner should be audited by the architect, whose certificate should be conclusive, gave a bond conditioned on his performance of the contract. He abandoned the work, and the owner completed it and sued on the bond for the cost of completing the work. Held, that the owner need not allege and prove that the certificate had been given as to the expense of completing the work.—Heidbrink v. Schaffner, 127 S. W. (Mo.) 418.

A building contract, providing that the owner on a certificate by the architect of the contractor's failure to perform any of the agreements may, on three days' notice, terminate the contract and complete the work, and that the expense incurred by the owner shall be certified by the architect, whose certificate shall be conclusive, does not provide against the contingency of abandonment of the work by the contractor, and where the contractor abandons the work the owner may complete it without obtaining the architect's certificate; the word "agreements" being synonymous with the word "stipulations."—Heidbrink v. Schaffner, 127 S. W. (Mo.) 418.

In proceedings to enforce a mechanic's lien for installing the plumbing and part of the heating apparatus in a building, the contract relied on consisted of the plans and specifications, the written bids, and the oral acceptance. The plans and specifications provided that the contract, when awarded, would be for a perfect job, even though every item required to make it such was not specially noted in the drawings or these specifications, and that the contractor should furnish all labor, tools, and appliances necessary to complete his work according to these specifications and perform the work in a true, workmanlike manner in every particular so as to provide the building with a durable and mechanically perfect system. Held, that the contractor was only required to prove substantial compliance with the plans and specifications in order to be entitled to a lien, and he cannot be held responsible for any fault in architecture, but only for faulty workmanship or material, or failure to comply with the plans. —Ruddy v. McDonald, 91 N. E. (Ill.) 651.

The mere delivery of material by a subcontractor to a contractor at the latter's place of business, the latter never incorporating it in the structure for which it was bought, or even delivering it on the premises or to the control of the owner of such structure, is not a "furnishing" of the material for, in, or about the construction of the improvement, within St. 1898, §3315, giving the subcontractor a lien for materials so furnished; the intent in that respect being shown by the concluding sentence, imposing penalty on a principal contractor, who without consent of and with intent to defraud a subcontractor uses, or causes to be used, material for an improvement other than that for which it was represented to be bought.—Francis & Nygren Foundry Co. v. King Knob Coal Co., 126 N. W. (Wis.) 39.

PATENTS.

The following list of recent patents and trademarks relating to building interests is especially reported for THE NATIONAL BUILDER by Wm. G. Henderson, solicitor of American and foreign patents and trademarks, Norris building, 501 F street, Washington, D. C. A copy of any of the United States patents will be furnished by him for 25 cents.

991,416. Sash-fastener. J. H. Bobbitt, Holstein, Neb.

991,371. Door check and closer. Jos. C. Reganassor, The Yale & Towne Mfg. Co., Stamford, Conn.

991,941. Chimney-top. Fred L. J. Boettcher, Washington, D. C.

991,768. Fire-escape. G. Busat, San Francisco, Cal.

991,605. Fireproof shutter. R. E. Byrne, assor. ½ to J. R. Cameron, Ottawa, Ontario. Can.

991,971. Reinforced concrete construction. Secondo Giletti, San Francisco, Cal.

991,635. Mold for concrete walls. A. C. Nielson, Chicago, Ill,

991,890. Sliding-door lock. Chas. F. Ritchel, assor. G. E. Greenbaum, New York.

991,755. Adjustable concrete form. B. F. Selbert, Mansfield, O,

991,674. Door-step. H. G. Voight, assor. Russell & Erwin Mfg. Co., New Britain, Conn.

992,733. Concrete construction. J. E. Gonzelman, assor, Unit Construction Co., Wilmington, Del.

992,554. Locking mechanism for emergency-exit doors. Edw. A. Freed, assor. 1-3 to F. Lundin and 1-3 to C. J. Forsberg, Chicago, Ill.

992,257. Fire-escape. D. J. Roche, Chicago, Ill.

993,227. Cellar door hinge. Jos. DeRose, Paterson, N. J.

992,760. Window screen. Chas. F. Dudley, Reading, Mass.

992,781. Door-operating device. Theo. P. Lallance, Huntington, W. Va.

992,812. Fire-proof door. Thos. P. Shean, Chicago, Ill.

992,996. Door-check. A. Stephan, Point Mills, Mich.

993,127. Wall construction. Robt. Tinsley, assor. The Pullman Co., Chicago, Ill.

PACIFIC COAST LUMBER MANUFACTURERS TAKE INITIATIVE IN TIMBER CONSERVATION.

The Pacific Coast lumber manufacturers have taken the initiative in an important step for the promotion of proper and conservative use of their timber supply. Practically all of the large manufacturers of lumber in the states of Oregon and Washington have entered into an agreement to manufacture odd, as well as even lengths in flooring, finish, and similar planing mill products. Heretofore, it has been customary to manufacture these products in even lengths only. Now, it is proposed to trim the manufactured lumber to lengths of odd numbers as well as even numbers of feet. Under the old system, a considerable portion of the lumber which came to the shaping machine was wasted and this action has been taken in order to save that waste.

Considerable opposition to this innovation has arisen among retailers and consumers. The retailer contends that it is impossible for him to dispose of odd-length material because of the common practice in the construction of wooden buildings, claiming that the initial saving of the manufacturer is transferred to the consumer. This is denied, however, because of the proportionally small amount of odd-length material which will occur under the new system, and because of the latter day practice of laying sub-floors of rough lumber and sheathing on the sides of the house before putting the finished material in place.

Because of the conservation element which enters into this question, the United States Forest Service has been recommending the adoption of odd lengths for some time past. The Portland office of the Service has recently made an investigation of the actual amount of unnecessary waste incident to the manufacture of even lengths only, and these figures show that under the old system the refuse burner consumed about two per cent of the total amount of the important forms of planing mill products which are manufactured from Douglas fir and other important forest species, in the states of Oregon and Washington.

When it is considered that about 750,000,000 feet of planing mill products are manufactured annually in the two states mentioned above, this two per cent assumes important proportions. The Forest Service is authority for the statement that 15,000,000 board feet of high-priced lumber can be saved annually in Oregon and Washington by the manufacture of planning mill products into lengths of odd feet as well as even. It would require the yearly growth of timber on approximately 30,000 acres of average timber land to produce the amount of lumber which this annual waste represents. The manufacturer is convinced that the waste is unnecessary. His greatest trouble now lies with a similar conviction on the part of the consumer, that odd lengths can be used as economically as even lengths.

MAXIMS BY MARK TWAIN

Noise proves nothing. Often a hen who has merely laid an egg cackles as if she had laid an asteroid.

Training is everything. The peach was once a bitter almond; cauliflower is nothing but a cabbage with a college education.

Habit is habit, and not to be flung out of the window by any man but coaxed downstairs a step at a time.

One of the most striking differences between a cat and a lie is that a cat has only nine lives.

The autocrat of Russia possesses more power than any other man on the earth; but he cannot stop a sneeze.

When I reflect upon the number of disagreeable people who I know have gone to a better world I am moved to lead a different life.

The true southern watermelon is a boon apart, and not to be mentioned with commoner things. It is chief of this world's luxuries, king by the grace of God over all the fruits of the earth. When one has tasted it he knows what the angels eat. It was not a southern watermelon that Eve took; we know it because she repented.

Be good and you will be lonesome.

Few good thinks are harder to put up with than the annoyance of a good example. It were not best that we should all think alike; it is difference of opinion that makes horses race.

Even the clearest and most perfect circumstantial evidence is likely to be at fault, after all, and therefore ought to be received with great caution. Take the case of any pencil sharpened by any woman; if you have witnesses you will find she did it with a knife, but if you take simply the aspect of the pencil you will say she did it with her teeth.

April 1. This is the day upon which we are reminded of what we are on the other three hundred and sixty-four.

The English are mentioned in the Bible: Blessed are the meek, for they shall inherit the earth.

Adam and Eve had many adventures, but the principal one was that they escaped teething.

There is this trouble about special providence—namely, there is so often a doubt as to which party was intended to be the beneficiary. In the case of the children, the bears and the prophet, the bears got more real satisfaction out of the episode than the prophet did, because they got the children.

There is no character, howsoever good and fine, but it can be destroyed by ridicule, howsoever poor and witless. Observe the ass, for instance; his character is about perfect; he is the choicest spirit among all the humbler animals, yet see what ridicule has brought him to. Instead of feeling complimented when we are called an ass we are left in doubt.

Consider well the proportions of things. It is better to be a young June-bug than an old bird of paradise.

Why is it that we rejoice at a birth and grieve at a funeral? It is because we are not the person involved.

All say, "How hard it is that we have to die"—a strange complaint to come from the mouths of people who have to live.

It is easy to find fault if one has that disposition. There was once a man who, not being able to find any other fault with his coal, complained that there were too many prehistoric toads in it.

When angry, count four; when very angry, swear.

The holy passion of friendship is of so sweet and steady and loyal and enduring a nature that it will last through a lifetime if not asked to lend money.

"Classic." A book which people praise and don't read.

The man with a new idea is a crank until the idea succeeds.

For two long hours he worked away
And shoveled to the street—
That night when he was fast asleep
It snowed about two feet!

Next morn, to get them clean once more,
He worked with might and main.
Came from the roof an avalanche
And filled them up again!

When ordered by the stern police,
Grim guardians of the law,
He shoveled out those walks once more—
And it began to thaw!

—Puck.

ATLAS OAK FLOORING.

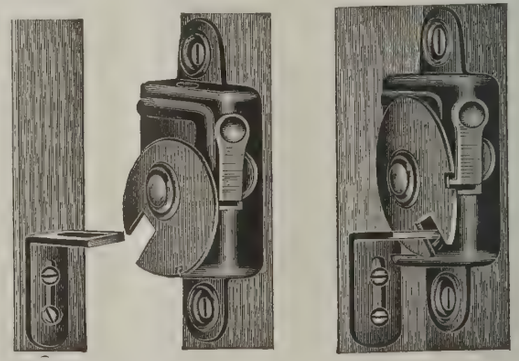
Not so many years ago very few contractors and builders paid much attention to finding out who were the manufacturers of the building materials they were specifying and buying. Anything that the dealer gave them in those days was accepted, and if anything went wrong the matter had to be adjusted with the dealer, and he had to take it up with the manufacturer. The contractor and builder of today insists on knowing who the manufacturer is, of all the materials he is buying. Where materials are trade marked, it gives the contractor and builder more confidence in them, because it is an easy matter to take up any complaint on any material direct with the manufacturer. Builders have learned that manufacturers who trade mark their goods and materials have to stand back of that trade mark and give the right quality.

The "ATLAS" oak flooring is a trade marked material. Every piece of "ATLAS" flooring is stamped with the word "ATLAS." The manufacturers stand back of this trade mark, and architects and contractors in specifying and buying it know that "ATLAS" must be right in every respect.

Many local lumber dealers are handling and carrying in stock "ATLAS" oak flooring, but where a dealer will not supply the demand and insists upon substituting some other flooring the manufacturers of "ATLAS" will see that the contractor who wants their flooring can get it direct.

All "ATLAS" 13-16 flooring is thoroughly kiln dried, dressed, and matched, hollow back, bored, end matched, steel polished and wire bundled. All "ATLAS" ⅜ flooring is thoroughly kiln dried dressed and matched, end matched, steel polished and wire bundled. In addition to wire bundling "ATLAS" ⅜ flooring the manufacturers also pack it in crates when desired at an additional cost of only $1.50 per 1,000 feet. This insures shipments being received in unusually fine and clean condition and is well worth the small additional cost.

"ATLAS" oak flooring is manufactured by the Wildberg Lumber Company, Ninth and Eggleston Avenues, Cincinnati, Ohio. They will be glad to give full particulars to architects, contractors and builders about "ATLAS" oak flooring.



WATROUS AUTOMATIC SCREEN DOOR CATCH.

The E. L. Watrous Manufacturing Company, of Des Moines, Iowa, has lately put upon the market a new Automatic Screen Door Catch, known as the No. 21. The Catch has a lot of good points, which they claim make it superior to any other on the market. Those which they most desire to emphasize are:

1st. The ease with which it can be set, as it comes flush on the door and needs no templet or diagram, which appeals to carpenters, as they do not like to "fuss" with a small piece of hardware, and have to make several trials before they get it on straight.

2d. The POSITIVE LOCK is an extremely desirable feature, making a secondary fastener unnecessary. Though they offer the Catch both with and without the lock, the overwhelming majority of their sales has been made on the Catch with the Positive Lock.

3d. They have retained on this Catch the adjustable strike,

which they found to be such a winner on their $5 Catch, and have made the metal nearly twice as heavy, so that this Catch is really a lock that will stand a great deal of abuse before it can be broken. No mere accident will put it out of commission, but anyone trying to break in would find it easier to break the door than to break this lock.

4th. It is good workmanship throughout, and it "looks like the Money." You will find no rough or split corners. They have introduced a special new embossing so that the cam cannot drag over to one side and bind, and altogether, it is a good piece of shelf hardware.

NEW SALES HEADQUARTERS.

J. A. Fay & Egan Co., the woodworking machinery people, announce the discontinuance of their Greensboro, N. C., agency. The Chattanooga, Tenn., office has also been discontinued and a new suite of offices opened in the Candler Building, Atlanta, Ga. The new Atlanta office will handle all business in the states of North & South Carolina, Tennessee, Georgia, Florida and Alabama (outside of Mobile). This merger was made in order that the business of J. A. Fay & Egan Co. might be done direct with the customer, insuring prompt and careful attention to each individual.

ASBESTOS "CENTURY" SHINGLES

"THE ROOF THAT OUTLIVES THE BUILDING"

Look into the service record of Asbestos "Century" Shingles for yourself. You'll find that you can depend absolutely on their integrity.

They give the client a roof that needs no repairing or painting—no expense bills that arouse his ill-will and make him question the value of every other feature of the building.

Asbestos "Century" Shingles are the first practical lightweight roofing of reinforced concrete—made of hydraulic cement reinforced with interlacing asbestos fibres.

Asbestos "Century" Shingle Roof—Residence of Dr. Thomas H. Bowman, Harrisburg, Pa.; Harry B. Shoop, Harrisburg, Architect; James M. Bowman, Harrisburg, Contractor.

These shingles are weatherproof, fireproof, timeproof. Cannot rot, rust, crack, split or blister. They literally outlive the building—without repairs or painting.

You can get Asbestos "Century" Shingles in shapes and sizes to fit any architectural scheme. Three colors—Newport Gray (silver gray), Slate (blue black), and Indian Red. Ask your Roofer for new quotations. Write for booklet "K. & M. 1911."

THE PULLMAN RAZOR STROPPER.

Were you ever shaved by a barber? Of course you were—and did you notice how he reached for his strop before he began to shave—once or twice while shaving you, and again before he laid his trusty razor down? Has it a poor edge to need so much stropping? No, it was the best he could buy, but it is necessary to strop the best razor frequently to keep it in shape.

You have a safety razor? Of course, almost every one has. But how about stropping? Do you use one blade three or four times, while the barber strops his a dozen, and then puts in a new blade—then get a dozen sharpened at once or buy new ones?

Why don't you give your safety razor as good treatment as the best common razor? Strop it at least before using, and just after.

You will be surprised at the result. But in order to strop the blade properly you must have a strop different from the old style.

The Pullman Mfg. Co., Rochester, N. Y., are placing on the market a new style of safety blade stropper, which permits the rapid sharpening of the blades. It consists of a handle having at the end a number of rollers through which the strop passes. The blade is clamped to a central bar, which is so adjusted as to hold the blade against the strop at the correct angle. The action of the strop automatically reverses the blade so there is no possibiliy of cutting the strop. The device is small, neat and compact and should last a lifetime. Every owner of a safety razor should have one.

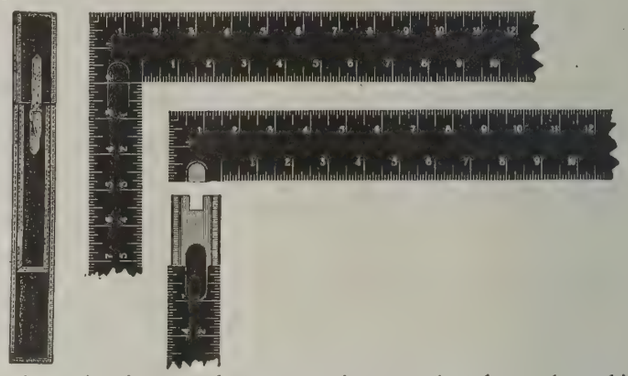
CONCRETE ORNAMENTAL MOULDS.

Never before in the history of concrete work has the use of concrete been so great for ornamental purposes as at the present time. There seems to be no limit to the possibilities in this line and concrete lends itself so readily to the manufacture of concrete articles that it proves most attractive and a very interesting line of work.

There is a satisfaction about turning out a handsome piece of work that appeals to every concrete worker, and the immense profits in this line are also very satisfactory.

You can make a vase similar to the following illustration with about one sack of cement. This vase would sell for not less than $5.00 and every housewife wants a pair of these as soon as she sees them. This illustration shows one of the most attractive and beautiful lawn vases on the market at the present time. It is sold by the Northwestern Steel & Iron Works of Eau Claire, Wis., who are extensive manufacturers of concrete machinery of every description and their catalogue shows the largest line of ornamental moulds made.

It will pay contractors to have a copy of this book if for nothing else than for reference. It describes everything shown in the concrete machinery line and gives valuable information of every description.



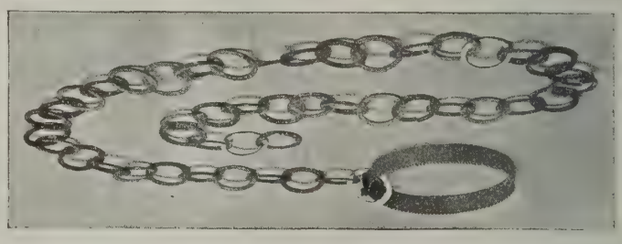
All moulds for ornamental purposes are made in four sections and are hinged so as to draw easily from the finished mould. The designs are clear cut and attractive in appearance and every contractor will do well to consider the establishment of an ornamental department in connection with their regular business.

Every article produced will prove an advertisement for their work and every live, up-to-date concrete man realizes that they cannot do business without advertising. There are a hundred and one different ways in which articles of this kind tend to bring added sales to their business, and will increase their profits to a large extent, and put their business on a more satisfactory and profitable basis.

THE NICHOLLS TAKE DOWN SQUARE.

The Nicholls Manufacturing Co., of Ottawa, Iowa, have recently placed on the market a new form of Take Down square, which possesses marked advantages over other forms now in use. In this square, the tongue separates entirely from the blade, so that there is no projection on the blade beyond the inside edge. This allows the square to be packed in a much smaller space, in fact, being only 2 inches by 24 inches. In putting together there are no screws or cams to adjust or come loose, but the tongue automatically locks securely into the blade without the use of any tools whatever.

One of the features claimed for this square is that it will always remain true, as the construction is such that the wear, occasioned by frequent taking apart, causes the two pieces to be more firmly held

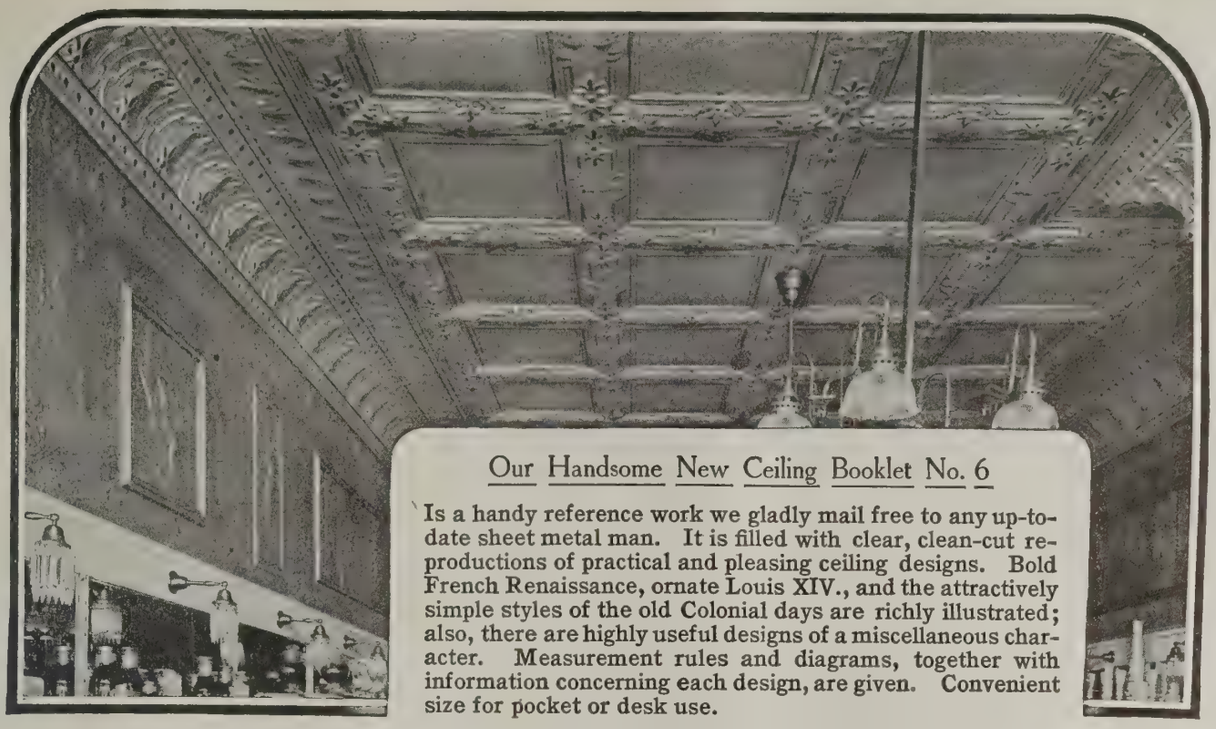


together. As the manufacturers make several styles and markings, this square can be obtained in the Nos. 3 and 100 Standard and No. 100 Rafter Framing in Oxidized Copper Black (white or yellow figures) Galvanized, Old Copper and Nickel Plated.

It will be noted that the No. 100 Rafter Framing Square has engraved on it the famous Nicholls Rafter Framing Rule, giving the cuts and lengths for common, hip, valley and jack rafters for seventeen different pitches. For those not familiar with this marking the Nicholls Manufacturing Company, Ottumwa, Iowa, offer to send a direction sheet describing their framing rule, as well as any other information regarding their famous squares.

FLEXIBLE HACK SAW BLADE.

This is not an illustration of a Dog Collar and Chain, but rather it shows the work of a Culley Flexible Hack Saw Blade, manufactured by the Simonds Manufacturing Company, Fitchburg, Mass., and Chicago, Ill. There were 47 separate rings made from a 1-ft. pipe, each ring slit and the chain formed. After making this num-



ber of cuts, the condition of the blade was so good that the teeth are clearly defined, even in this greatly reduced illustration. The remarkable flexible property of this blade is shown by its being bent in a complete circle.

HAVE YOU INVESTIGATED AMATITE?

Nobody who is buying ready roofing from time to time has any business to be ignorant of the fact that there is a very large and rapidly increasing amount of no-paint roofings coming into use. The painting feature was the only objection to the old-style smooth-coated roofing. Painting cost money and was very apt to be neglected in the interests of other matters that were more pressing—then, before the owner woke up, the roofings had begun to lose their waterproof characteristics, were absorbing water and being injured by frost. Accordingly, the advent of Amatite, with its practical mineral surface, was hailed with much satisfaction by ready roofing users, and the sales of the new invention have been increasing with tremendous rapidity. The simple fact that Amatite Roofing costs no more than the painted kind, will last as long and longer, and involves no maintenance expense whatever, made it a favorite with building owners all over the country.

Simply as a matter of relative economy and satisfaction, look up Amatite. You can do so very easily by simply addressing a request for a sample to the nearest office of the Barrett Manufacturing Company, New York, Chicago, Philadelphia, Boston, St. Louis, Cleveland, Pittsburg, Cincinnati, Kansas City, Minneapolis, New Orleans, Seattle.

Our Handsome New Ceiling Booklet No. 6

Is a handy reference work we gladly mail free to any up-to-date sheet metal man. It is filled with clear, clean-cut reproductions of practical and pleasing ceiling designs. Bold French Renaissance, ornate Louis XIV., and the attractively simple styles of the old Colonial days are richly illustrated; also, there are highly useful designs of a miscellaneous character. Measurement rules and diagrams, together with information concerning each design, are given. Convenient size for pocket or desk use.

We will mail your copy tomorrow if your address reaches us by that time.

IDEAL IDEAS.

The May number of Ideal Ideas, published by the Ideal Concrete Machinery Company, of South Bend, Ind., and London, Ontario, Canada, shows the results of their recent prize competition for completed buildings.

Owner, Judge Smith, Trust Building, Ottawa, Canada; architects, The Bungalow Craft Company, Los Angeles, Cal.; contractors and block layers, Boyd Brothers, Osgoode, Ont. Erected at Brittannia Heights; frontage, 38 feet; depth, 38 feet; 1,850 8x8x16 inch faced blocks of rock and panel designs used. Building has concrete foundation, 9 rooms, hot water heat. Cost of block work, $750; cost of building complete, $5,400.

Through the courtesy of the Ideal Concrete Machinery Company we are able to reproduce the photograph receiving one of the prizes. There were several hundred entries from all over the world, and the prizes were distributed to Scotland, India, the Philippines, as well as Canada and the United States.

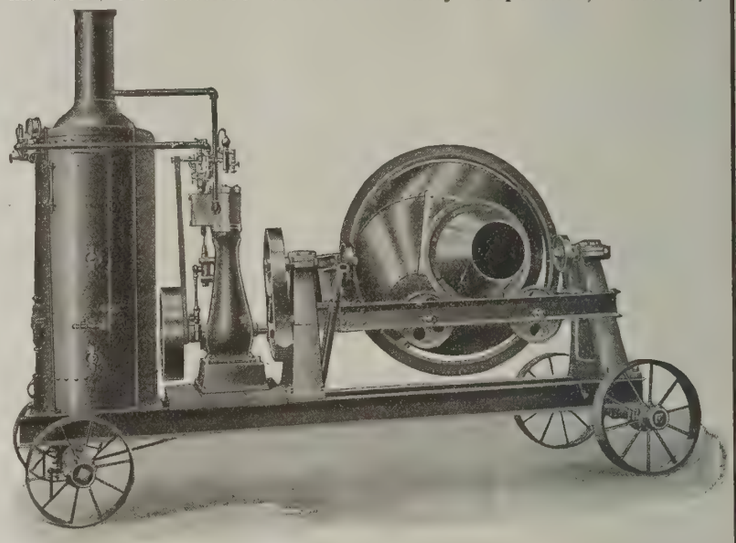
The purpose of the contest was to show something of the unlimited possibilities and great range of opportunities for the use of Ideal Concrete Blocks, and the results justified their most sanguine expectations. Many sent photographs showing the progress of their work, asking that they be not entered in the contest as their work was not as good as they expected to have it in a short time.

The contest emphasized the fact that while many were making blocks, they were not taking the care they should to secure work of the best quality. The workmanship in laying was in many cases not up to the standard, as one block mason was told when in quest of new work: "Of course, concrete blocks are all right—they may be waterproof, fireproof, vermin proof, repair proof, everlasting. and all that, but look at So-and-So's concrete block house, with its uneven mortar joints and the dauby work of the mason. It is fine inside, but outside it is a fright." The difference in care in just this point is largely responsible for the United States obtaining only five of the sixteen prizes.

We believe that any reader of THE NATIONAL BUILDER can obtain a copy showing the prize buildings by writing to the Ideal Concrete Machinery Company, at South Bend, Ind., or London, Ontario, Canada. Ask for Number 12, Volume I of "Ideal Ideas."

ANTI FRICTION BALL TIP BUTTS.

Builders are fast appreciating the solid merits of Butts equipped with accurately fitted Anti Friction Washers of a special metal, preventing any possible wearing away of joints, and in addition have a patented Non Rising Pin eliminating all trouble incident to partially lifted pins. Doors fitted with the McKinney Anti Friction Ball Tip Butts always swing freely and noiselessly, regardless of their weight.

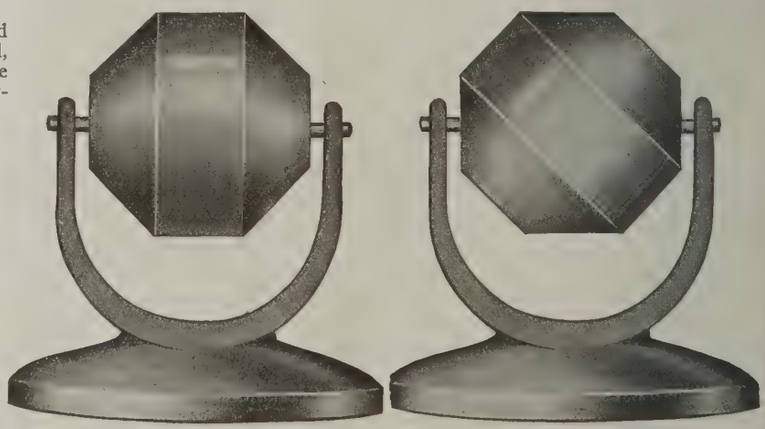


Although these Butts represent quality in every detail, their cost permits of their being used on medium priced buildings as well as the most expensive. The guarantee of the McKinney Mfg. Co., Pittsburg, Pa., represents a house of forty years' standing, owning one of the largest and best plants in the world. Strap Hinges, Barn Door Hangers, Track, etc., are also made under the same valuable guarantee. Their goods in all sizes and standard finishes are to be had of most hardware dealers, and builders and contractors are invited to send for the new 1911 catalogue and to ask their dealer for McKinney's Butts.

TRADE McK MARK

A NEW METHOD OF MIXING CONCRETE.

Engineers and architects are daily becoming more exacting in their requirement in constructions. The unquestioned efficacy of machine mixed concrete has the effect of specifications reading "all concrete must be mixed by machine." In order to get the best work, the contractor must show that he is accustomed to mixing by machine, and in order to carry out the work to advantage, he must use the mixer. So, the question is not a mixer, but which mixer is best for the character of work the contractor is building. The contractor on sidewalk work does not need, in fact, cannot use to advantage, the large mixer used in heavy foundation work.



That the intending purchaser may decide which mixer to use in his work, the Waterloo Cement Machinery Corporation, Waterloo,

Iowa, have prepared appropriate literature describing the Polygon Mixers, Hoists and Contractors' Equipment. By the study of this catalog, the contractor is able to see how a slight expenditure for "permanent plant" is able to save money on even the smallest contracts. The use of a mixer stamps the contractor as progressive and will often obtain a contract at a preference in price.

In the Polygon mixers a new method of mixing concrete is used. This can readily be seen by reference to the cuts shown herewith.

In the Polygon, the shape of the drum provides all the mixing action necessary. When the drum containing a batch of concrete is revolved, the materials are thrown from one side to the other—endwise, sidewise, crosswise and everyotherwise. The process of mixing is thorough and rapid. The complete mixing of all the materials adapts it for dry as well as wet mixtures, and for aggregates of varying sizes. As the principle of mixing requires that every particle of material shall be uniformly coated with cement, it will be

seen that the "Polygon way" is close to the theoretical ideal.

The manufacturers claim that the concrete mixed by this method has a clean, smooth appearance, indicating the thoroughness of the mix.

While the Waterloo Cement Machinery Corporation makes a large list of mixers of various sizes and capacities, it is only necessary to show one in these columns. The machine must be portable and self-contained, and as shown, is ready for the severest work. When equipped for steam in this way, the boilers are made to meet the various state and city ordinances regarding the use of steam boilers. When desired a portable canopy can be added, protecting the engine and apparatus from the weather. Gasoline engines may be used, the nature of this power being particularly adapted to situations where the work is intermittent.

Interested readers of THE NATIONAL BUILDER are requested to write The Waterloo Cement Machinery Corporation, Waterloo, Iowa, for the complete catalog showing all the styles of mixers and other contractors' machinery.

We Want A Builder In Every Town

We Have an Attractive Proposition for One Carpenter or Builder in Every Community to Take Orders for Our Widely Advertised

EDWARDS' METAL SPANISH TILE

ARE EASILY SOLD BY OUR AGENTS

Home Owners Everywhere Are Reading Our Advertisements in the Leading Magazines

EDWARDS' INTERLOCKING METAL SPANISH TILE

ARCHITECTS EVERYWHERE SPECIFY THIS ATTRACTIVE ROOFING

Edwards' Metal Spanish Tile are stamped out of the highest quality Worcester Grade Terne Plate, size 10 x 14 inches, furnished either painted or heavily galvanized. They are provided with our patented interlocking device, which conceals all nails, makes it possible to get a perfectly moisture proof roof without **soldering** and without danger of having the tile crack open in extreme cold or hot weather.
Edwards' Metal Spanish Tile looks exactly like the best Terra Cotta Tile. They have the decided advantage of being much lighter, easier to apply, longer lived and cost much less.

Write us today about your territory. Here's an opportunity you should not miss. Many carpenters and builders have been so successful taking orders and laying our Metal Spanish Tile that they now devote their entire time to this business. Others have made big profits selling and laying our metal tile roofing "between jobs." We show you how to build up an independent, profitable business in your own community. Write for our proposition today. The territory is going fast. Don't be too late. Send a postal right now.

A MEASUREMENT DIAGRAM FOR METAL CEILING USERS.

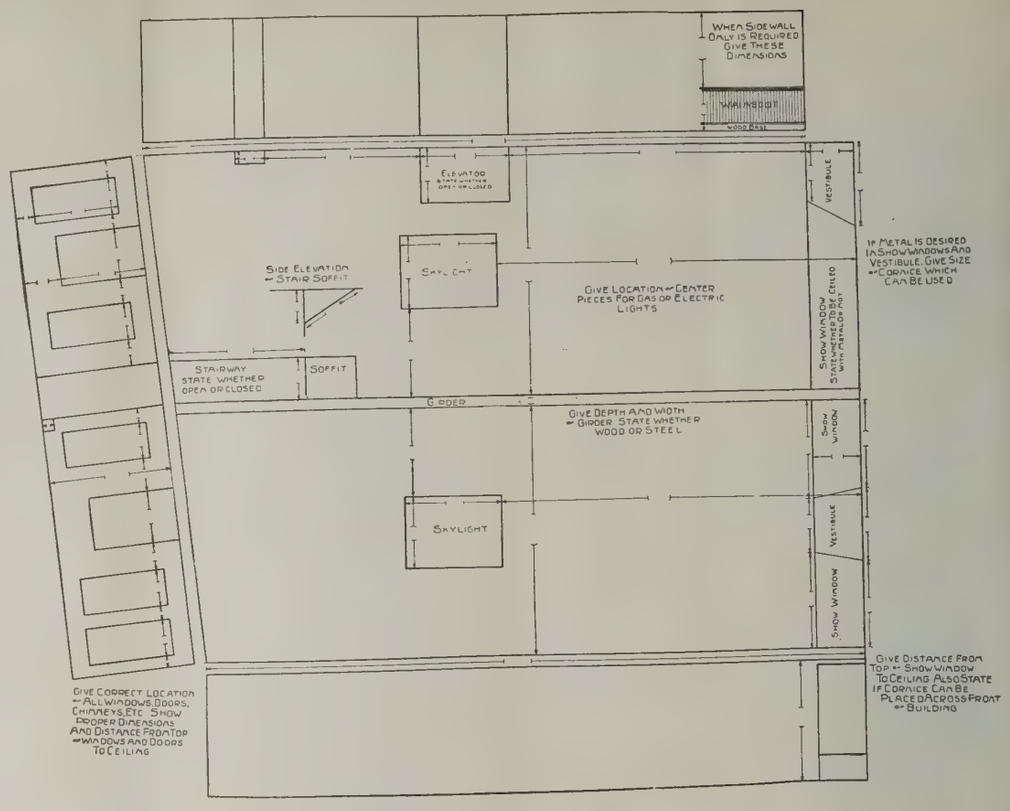
Through the courtesy of The Empire Iron & Steel Company of Niles, Ohio, we have been permitted to print the following measurement diagram and data from that company's ceiling catalogue No. 6, which is now being distributed without cost to interested parties. We recommend that this article be clipped and filed for reference by those of our readers who have occasion to handle metal ceilings.

The diagram is self explanatory and if followed faithfully the resultant measurements will insure a perfect fit of all parts of the ceiling and consequently an attractive job. The rules given in addition should also be carefully noted.

RULES FOR MEASURING.

To the actual length of ceiling to be covered add the depth of cornice on each end wall. To the actual breadth of ceiling to be covered add the depth of cornice on each side wall. The actual Metal Ceiling required is found by multiplying these two results. For instance:

Length of room, 62', plus depth of Cornice, both ends, 16" + 16" = 64' 8".



Breadth of room 20', plus depth of Cornice, both sides, 16" + 16" = 22' 8".

64' 8" × 22' 8" = 1,466 square feet of Metal Ceiling required.

Deductions are allowed only for large openings of 75 square feet or more, since fitting around openings is as expensive as covering them.

Beneath each combination illustrated in this catalogue is noted the depth of Cornice.

Measurements of both sides and both ends should be given, as rooms are frequently out of square. Be sure to locate doors, vestibules, chimneys and offsets, on a sketch to be sent with order or inquiry. Give the height of walls, and, separately, of the baseboard. All such fixtures as gas or electric-light drops must be placed so as to conform with the drawing and arrangement of the Ceiling.

MEASUREMENT DIAGRAM

UTILITY CRACK FILLER.

The greatest objection to the use of wall board has always been due to the fact that so many builders do not like to have to panel the walls and ceilings in order to take care of the joints between the sheets of wall board.

The Heppes Company, of 4502 Fillmore street, Chicago, Ill., have perfected an elastic filler known as Utility Crack Filler, which, when used to fill the cracks between the sheets of Utility Wall Board, manufactured by the same concern, entirely eliminates this objection.

Utility Wall Board, having practically no contraction and expansion when applied to the walls and ceilings and the joints filled with Utility Crack Filler, make a smooth surface on which wall paper or burlap can be successfully applied.

The Heppes Company is known as one of the most up-to-date manufacturers in the country, and this recent improvement, together with other important features of Utility Wall Board, makes it one of the most popular building materials known to the contractors, builders and architects of this country.

If you have never seen a sample of this economical, durable and artistic wall lining, it will pay you to write them for a sample today. It's worth your while.

Complete information concerning Utility Wall Board and Utility Crack Filler may be obtained by addressing The Heppes Company, 4502 Fillmore street, Chicago, Ill.

WATERPROOFING MATERIALS WELL WORTH CONSIDERING.

Among the many different brands of waterproofing materials now on the market, the H. W. Johns-Manville Company, 100 William street, New York, are offering a line of fabrics, felts, cements and coatings know as J-M Waterproofing Materials.

These materials, which are the result of this firm's half century of experience, careful study and unexcelled facilities, are especially made to meet every condition in waterproof building construction and have been effectively used for waterproofing underground tunnels, walls of brick and concrete buildings, dams, reservoirs, swimming pools, etc., with much success.

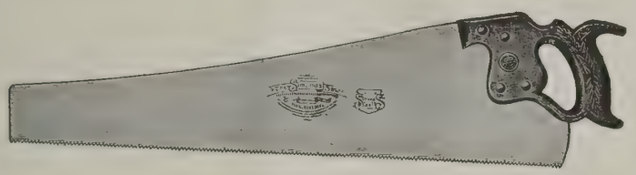
J-M Waterproofing Fabric is strong, loosely woven burlap impregnated with pure asphalt. The asphalt not only clings, but becomes locked into the fabric, and it is claimed that a few layers of this fabric makes a waterproof course of great strength, ductility and elasticity that remains intact and resists moisture even when cracks occur in the cement work.

J-M Waterproofing Asbestos Felt is made of pure asbestos fiber, thoroughly impregnated with pure asphalt. This fabric, being composed of only mineral substances, contains nothing to decay or deteriorate, and is therefore best adapted for waterproofing all exposed and foundation construction work. In addition to being waterproof, it is also positively acid, mould and rot proof. The asphalt is of a peculiar nature, and has wonderful cementitious characteristics. It is used cold and hot and does not run, shove or creep, and will not become brittle in high or low temperature.

This combination produces a waterproofing fabric that is especially serviceable where continual dampness prevails.

One of the most perfect water and dampproof materials made by this concern is their J-M Waterproof Coating. This is a combination of carefully selected materials of the highest grades, which, when applied, makes a film unimpenetrable by moisture. Aside from being inexpensive, it does away with furring and lathing and makes a positive bond between plaster and brick or stone walls. This coating protects plaster from strains due to dampness, also from discoloring by fireproof tile walls. Damp cellars and walls coated with this coating are made clean, sweet and useful. This coating can also be used in place of so-called non-straining cements, for stain-prooving marble, granite and limestone.

This concern has issued a little booklet explaining fully the merits of their waterproofing materials, which they will gladly mail to anyone on request.



HY-RIB.

Under this appropriate heading, the Trussed Concrete Steel Company, Detroit, Mich., are sending out the sixth edition of their Hy-Rib handbook, showing the value of this fabric in all parts of buildings of various characters and particularly for use in the construction of silos, tanks and conduits.

For the convenience of the reader, the book is subdivided into various sections, such as that for General Data on Hy-Rib, Applications to Floors and Roofs, to Walls and Sidings, Partitions, Ceiling and Furrings, Building Construction in General, Special Tools and Clips for Hy-Rib, etc. The detailed working drawings show exactly how the material is applied to building work. Illustrations are made from photographs showing the use of the material in construction.

Only those directly connected with the building trades have a conception of the manifold uses to which concrete, and especially re-enforced concrete, is being adapted. Not only in massive foundation work to support heavy structures, but in the walls and partitions as well. The danger from fire, as well as natural deterioration and decay, is causing engineers and architects to adopt it more and more in places where it is necessary to balance tects t oadopt it more and more in places where it is necessary to balance the naturally great comp.essive strength of the concrete by adding metal re-enforcement. Such places as walls, partitions could be built of solid concrete, but in order to be stiff enough would have to be very thick and bulky. The addition of re-enforcement allows a much thinner and lighter wall. In the proper design of structures where a thin wall or partition is desirable the engineer has a wide opportunity to display his ingenuity. To aid him this book is prepared.

WHY NOT GET A SI-MONDS HAND SAW FOR YOUR WORK NOW?

You have read so much and heard so much about the Simonds Hand Saw that now it is time for you to try it.

Remember that the dealer who sells you a Simonds Saw is empowered to guarantee it fully in every respect and your money will be refunded if the Saw is not entirely satisfactory.

Remember that there is a variety of styles from which to choose; different lengths, points, straight back or sway back.

Remember the Simonds Hand Saw is made of Simonds Steel and each Saw is packed in a separate case—a distinctive feature.

Remember that the workmen who make Simonds Saws are the most skilled men at this trade.

If it will help you we will tell you the name of the dealer near you who sells Simonds Hand Saws, or, if there is none near you, we will quote you a price on a saw delivered direct from the factory. Just fill in the coupon below, clip it out and mail it to us. The quickest way to get a Simonds Hand Saw.

Sheath Your Houses With LINOFELT

Linen-Felt made from Flax-Fibre

38 Times More Effective Than Building Paper

BUILD houses that keep the outside *out* and the inside *in*, that keep *out* the cold of winter and the heat of summer, that keep *in* the warmth in winter and the cool in summer. Put up houses and buildings that keep out sound, the rooms of which are quiet and restful. Getting these features will add less than one per cent to the cost of your house, will add more than 40% to its comfort and living value and will effect a constant saving of 40% in all fuel bills. Architects, contractors and carpenters are the ones able to appreciate most the superiority of **Linofelt** because they know how unsatisfactory is ordinary building paper.

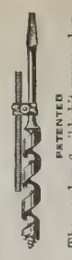
These Plans Show The Method

They show you clearly the practical and simple method of insulating walls and floors with **Linofelt.** Every carpenter, every builder, every architect realizes just what these little plans mean. They are keen to the advantages of building according to these methods. They know how important such efficient insulating of walls, floors, ceilings and partitions is to *all* classes of homes and buildings. We might emphasize residences, office buildings, hospitals, school buildings, stores, and buildings constructed for manufacturing purposes. These must have the uniform warmth in winter, coolness in summer and the quiet all the time that **Linofelt** insures.

Anyone who knows **Linofelt** immediately becomes enthusiastic about it—because it has so many delightful features. It is an insulating quilt. No other is as light as **Linofelt** cubical contents considered. It comes from the same source as linen. It is made from flax in the largest flax market in the world—Winona. It is odorless, chemically clean, as sanitary as a surgical dressing.

We have had made comparative tests of **Linofelt** and other sheathing mediums for sound deadening qualities. We will send them on request. The same sound heard 200 feet through ordinary building paper is heard only 2 feet away through **Linofelt.** Tests prove **Linofelt** more than 38 times as effective as building paper for all uses.

Let Us Place All The Data In Your Hands



Let us send you an attractive book for Architects, Contractors and Carpenters showing **Linofelt** in all forms, telling how it is made, showing and explaining plans and methods of using **Linofelt,** illustrated with excellent photographs of residences and buildings built with **Linofelt,** located in different climates. Let us send you this meaty book because it also tells in like manner of Lith Board and Rock Wool. Let us acquaint you with our Service Department, our own engineers, who have a world of experience in insulating work, who have pursued it under all sorts of conditions for a great many years, who are fully equipped and qualified to be of the greatest assistance to you in your work, whom you can consult at any time regarding any of your work *gratis.* Let us send you a **free** sample of **Linofelt** so that you can see it with your own eyes and feel it with your own hands and have a close realization of its extreme effectiveness, have a firm knowledge that it will do *more* than we claim it will do. Get the book, the service, the sample by writing to us today. **Please ask us for the name of the dealer nearest your home.**

BUNGALOWS

Over 4,000 Builders and Architects bought copies of the second edition of "California Bungalow Homes" during 1910. Half of them wrote back that the book was worth many times its cost. New (3rd) edition is just ready. Price $1.00 postpaid. Send for a copy. The Bungalow *is the thing*, and this is the only book published which shows the REAL California Bungalow inside and out. Better send at once.

Smaller book, showing 38 Bungalows and floor plans, 25 cents postpaid.

The Bungalowcraft Company, 407 Chamber of Commerce, Los Angeles, Cal.

Cassens Ideal Eaves Trough Takes Water Only

The Ideal completely overcomes the disadvantages of the old style open gutter. It satisfactorily catches and carries away the water that falls on your roof. Its use insures clean, healthful cistern water. Leaves, trash, gravel, etc., cannot enter it. Neither can birds build nests in it. Therefore it is never clogged. Ice will positively not break down the trough

A unique and important feature of the IDEAL is that it will not fill with snow and ice. When it sleets the small opening (about one-eighth inch) is quickly closed. This prevents the bursting of the trough, also of the down spout. When it thaws the ice melts, and the entrance opens automatically before the water from the roof reaches it.

The Ideal can now be erected with a Wire Hanger if face-board has mouldings.

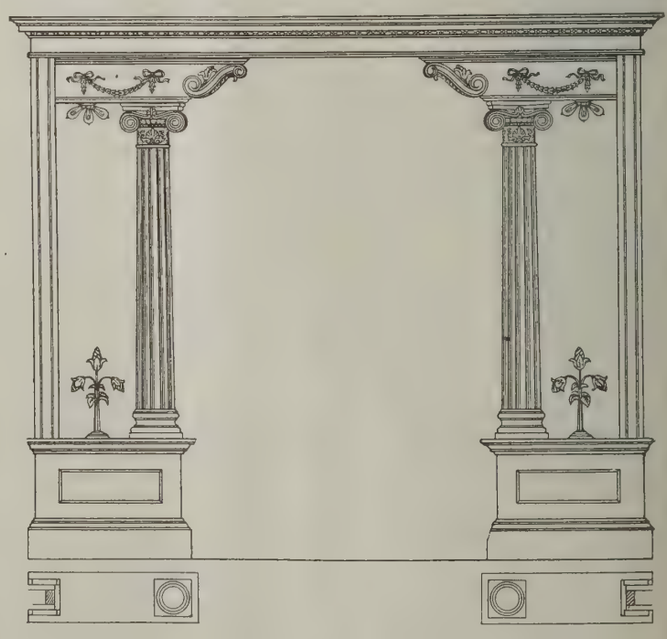
CASSENS MANUFACTURING CO., Edwardsville, Ill.

THE GALE WALL SAFE.

To protect one's valuables, we must consider the dangers which confront them. There is the ever present danger of burglars and petty thieves, and there is the constant danger from fire. There is also the danger of valuable papers being lost through misplacement in books, files, drawers, etc. At house cleaning time, little effort is made to carefully look over large bundles of papers, boxes, etc., but it is left to chance that no valuables are thrown out.

Protection against all of these dangers can easily be secured in large, cumbersome safes or vaults, but the average householder or tenant has no such amount of valuables as would warrant the purchase of such large pieces of equipment.

For the convenience of those wishing a safe place for ordinary valuables, papers, etc., the Willis Manufacturing Co., of Galesburg, Ill., are making a wall safe of unusual merit. They are made in several sizes, having a capacity of from 320 to 880 cubic inches, and are intended to be built in the walls or partitions of either frame or brick houses. When installed only the circular door is exposed,



having a three tumbler combination lock of improved mechanism. The makers claim the locks are unpickable and are capable of an indefinite number of changes.

For protection against fire, the safe is lined with asbestos lumber, which, with the resulting air-spaces, insures perfect safety.

Don't leave your valuable papers, notes, receipts, etc., lying around where they will get lost or destroyed. Write to the Willis Mfg. Co., Galesburg, Ill., and get their information and prices on the Gale Wall Safe.

GRILLES, COLONNADE OPENINGS AND CONSOLES.

The catalogue number 19 of the Chicago Grille Works, 826-836 Wells St., Chicago, Ill., shows an excellent line of grilles, parlor colonnade openings, consoles, etc. The experience of the Chicago Grille Works in this line of material is based on many years of manufacturing and designing. They have always kept up to date in designs and have never cut down the size of the columns used in their openings from what they should be to mere curtain poles. They have always manufactured from the best materials and the sizes of columns, dowels, etc., have always been in proper proportion no

matter if this did mean a little more expense to them in getting the work out.

The policy of the Chicago Grille Works has been to give their customers the best materials, prompt shipment and fair treatment in every way and there are many of the best contractors and builders, not only in Chicago but in many other cities and towns, who will thoroughly agree to these claims.

The accompanying plate number 102-C.-18 illustrated here shows that the Chicago Grille Works is giving special attention to electric wiring, the connections being shown both on the pedestals and on

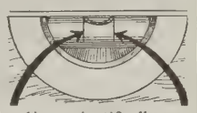
AKRON LEVELS DON'T BREAK

When you buy an Akron Level, you get one that you can be as careless with as you like—it won't break every time you accidentally drop it.

Study the construction of an Akron Level and you'll instantly see that the Akron is the strongest and most substantial level ever made. They're designed to stand the falls and jars incidental to daily use without danger of breaking.



Instead of a thin, easily broken spirit tube, as most levels have, the Akron has a double spirit tube. The inner tube is as heavy and strong as ordinary levels have and it is protected and made doubly strong with an outer tubing of heavy steam gauge glass, with elastic rubber bearings between the two tubes.

This one feature alone should warrant you in buying an Akron Level, but there are several other equally strong reasons why the Akron Level is best of all. For instance:

Here is the Exclusive Easy Reading Feature

The two fine silver lines around spirit tube, one at either end of bubble when it is exactly in the center, makes the Akron the easiest-to-read level in the world. No other level has this exclusive feature which shows L-E-V-E-L, or otherwise, instantly, and can be seen at a considerable distance. No other level is so scientifically accurate, or so well adapted to every use that a level can be put to.

Akron Eclipse Levels are made in 33 styles and sizes for carpenters, masons, concrete men and everybody who uses a level.

And yet, with all the big advantages possessed by Akron Eclipse Levels, they cost no more than the ordinary kind.

Sold by Hardware Dealers Everywhere

If your dealer does not sell Akron Eclipse Levels, write us for catalog, mentioning your dealer's name. You want the best level that money can buy, so find out about Akron Eclipse Levels before you purchase. Write us today. A postal will do.

the beam brackets. Plate No. 55-C.-18 shows a neat arch design for an opening between a stair hall and parlor, where a little more privacy is needed by the home owner. This arch, as well as the other, is made in various widths and heights, each in proportion to the open-

ing to be filled. The catalogue is issued by the Chicago Grille Works shows many other fine designs, such as these two, and can be had to make selections from upon request.

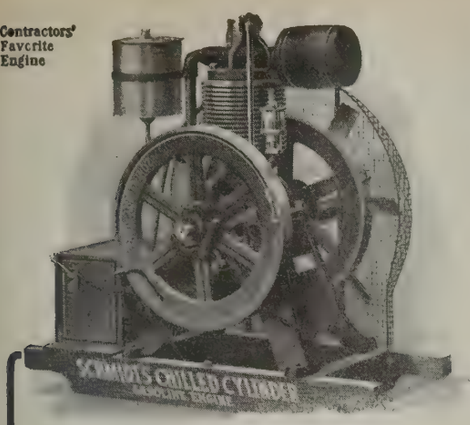
AUTOMOBILE TURNTABLES.

In the construction of a small garage a turntable is a great convenience, in a large one it is necessity. This statement would apply nearly as well to stables, where most of the readers of THE NATIONAL BUILDER are familiar with the efforts necessary to turn carriages around in close quarters.

As manufactured by the Lansing Wheel-Barrow Company. A turntable is not a difficult piece of equipment to install and the simple construction insures freedom from repairs. When properly installed, the table can be used as a wash stand, the water running freely over the smooth top and finding its way out through a trough at the edge of the pit.

Nor is it necessary to put the turntable in the garage. It can with equal facility be placed in the driveway in front of the door; this allows one to drive into the garage when in a hurry, or if time permits the car can be turned before entering the garage, and to be ready for leaving the garage under power.

The use of a turntable is more than a matter of convenience. A large part of "tire trouble" results from turning and twisting the car in cramped quarters, such as are usually met with in the cities. The cost of repairs due to a slip on a dark night, tearing off the doors



of the garage or smashing the top or guards will soon equal the cost of the turntable. The approach to the garage is not always a broad level stretch. Only too often there is a sharp turn or a steep grade with obstacles on one or both sides. A turntable is then the only practical solution.

When the garage must open directly on the street, as it must in most city garages, the danger not only to the street traffic and pedestrians but to the automobile itself, makes a turntable a real investment. A backing automobile receives scant courtesy especially when unnecessary, and these trouble are entirely preventable.

If you neglected to install a turntable when you built your garage or if you are about to build one, write to the Lansing Wheelbarrow Company, Lansing, Michigan, and ask for "Talks on Turntables." You will find it interesting and instructive.

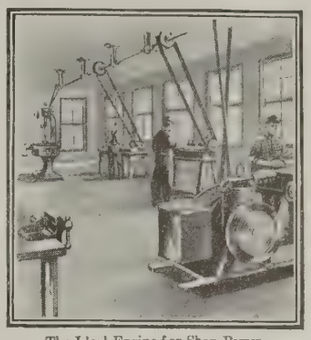
Contractors' Favorite Engine

$7.50 and You Keep This Great Engine

Yes, sir, that's right—you keep this engine for $7.50, a wonderful gasoline engine offer, an offer without a parallel. We ship you Schmidt's Chilled Cylinder Gasoline Engine on your simple request without an order or any promise from you. You use the engine 10 entire days, use it all you want to. Then if you don't want it, send it back at our expense. If you do wish to keep it, pay us **only $7.50 and the rest in the easiest monthly payments. We send you the engine free,** to prove that it is the greatest **air cooled** 3-horse power engine on earth. It is the only engine with the marvelous, powerful **chilled cylinder.** The only small engine with a **spark retarder.** The new type gasoline engine that has revolutionized the gasoline engine industry. The only engine good enough to send out on **actual free trial** without a cent down in any way.

Ten Days' Trial FREE—This is the first genuine free trial ever offered on gasoline engines for farm and shop use. We want you to see that women and children can run this engine. Use the engine to run any machinery you have—the pump—lathes—saws—drills—hoists—concrete mixers—anything. Engine is ready to run when you get it. We will send you prepaid our sensational offer and our very useful book, "How to Use Power," free.



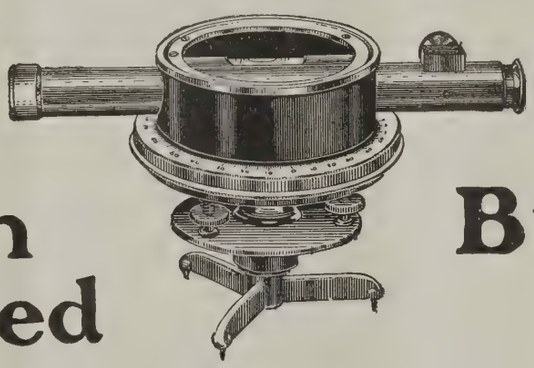
5 Years Guarantee—Schmidt's Chilled Cylinder Gasoline Engine is absolutely guaranteed for 5 years in every piece and part. The biggest bank in Iowa backs our $1,000 challenge offer.

Long Time to Pay

If you like this engine after trying it out for 10 whole days you can keep it and take long time to pay for it on **easy monthly payments,** or after using it free for 10 days, just send it back at our expense.

How to Use Power

To all who will write promptly we will send our useful book, "How to Use Power," free. Send us your name and address today.



The Ideal Engine for Shop Power

SEND NO MONEY—Don't send us a cent when you ask us to ship this engine. Remember it is air cooled and the easiest engine to handle.

Schmidt Bros. Co. Engine Works, Dept. 697X, Davenport, Iowa

EVERY CONTRACTOR

LARGE OR SMALL WOULD BUY A

Bostrom Improved Builder's Level

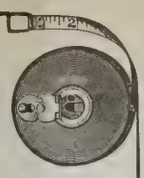
If he would just drop us a line to ship him one for inspection and approval. We say that because we have never known a Contractor, Builder, Architect, Surveyor, Civil Engineer, or even Instrument manufacturer to inspect a BOSTROM LEVEL who did not concede that at the price there had been nothing yet produced which would compare with the Bostrom in all the necessary essentials of a simple, accurate, durable and throughly dependable Level

Another thing, the Bostrom Level possesses means of adjustment for proving its accuracy, not surpassed by the highest priced Engineer's Level, and this principle is applied in such a novel and simple manner that even the inexperienced operator can **prove his work right on the spot,** and it can be done in a mere fraction of the time required to prove the accuracy of any other level, regardless of the price.

You have to examine the Bostrom Level to appreciate all of its merits, but the above feature alone makes sales on sight, and a sale always means a Bostrom endorser.

We back up every statement we make with a GUARANTEE of satisfaction or money back.

Our terms are cash with order, or shipment made C. O. D. SUBJECT TO EXAMINATION. Prices: No. 3, $25.00; No. 4, $30.00, f. o. b., Atlanta. Shipping weight 15 lbs., and complete outfit includes Level, Tripod, Graduated Hardwood Rod (not furnished by any other manufacturer without extra charge), Target and Plumb-bob, Trivet, and neat oak box for keeping Level when not in use. Eyepiece in No. 3 Telescope has magnifying power of 10 to 12 diameters, with sliding focus; and eyepiece in No. 4 Telescope has magnifying power of 18 to 20 diameters, with rack and pinion focus.



If you are needing Level at once, order direct from this article, as we do not even require you to guarantee express charges (and no other instrument manufacturer ever made such an offer). We don't hesitate to do it, as we have shipped thousands of Levels in that manner, and the enthusiastic endorsements of these purchasers gives us the unlimited confidence that the Instrument will please you. If you are not needing Level right away, write for full description and get acquainted with the Bostrom before buying. Bostrom's Levels are used and endorsed in every State in the Union, and are rapidly taking the place of instruments much higher in price, and you owe it to yourself to inspect the Bostrom before buying.

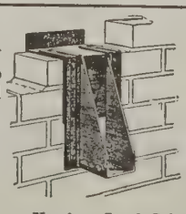
Topp's Framing Tool
A PERFECT TOOL, AND THE ONLY TOOL FOR THE PURPOSE EVER INVENTED

PRICE, $1.75



Saves from 3 to 24 hours in laying out a single roof. Saves time for the skilled mechanic, and enables the ordinary workman to frame the most difficult roof with absolute certainty.

IT DOES ALL THIS
It is accurate, thus preventing all mistakes.
It gives angles for any pitch.
It gives lengths for any rafters.
It gives cuts for principals, jacks, hips, valleys and cripples.

CORTRIGHT METAL SHINGLES.

Practically every reader of THE NATIONAL BUILDER is interested in roofing, and we are pleased to be able to announce that the Cortright Metal Shingle Advocate will be sent free for one year by the Cortright Metal Roofing Co., 50 N. 23rd St., Philadelphia, Pa. The fact that an American home catches fire every three minutes, should lead everyone to try to reduce the fire risk. A large, too large, proportion of fires start from the roof, and by making that part of the building incombustible as well as rain and wind proof, the metal shingle is doing excellent work.

Remember, you can get your name on the list free by mentioning NATIONAL BUILDER to the Cortright Metal Roofing Company, 50 N. 23rd St., Philadelphia, Pa.

CANADA'S ASBESTOS SUPPLY.

[From Consul A. E. Seyfert, Owen Sound, Ontario.]

According to an official report, Canada produces 82 per cent of the world's supply of asbestos. The companies operating asbestos quarries and factories in Canada are capitalized at $24,290,000. In 1880 only 380 tons of asbestos were produced in the Dominion, valued at $24,700; in 1909 the output was 63,300 tons, valued at $2,300,000. In 1909 2,000 men were employed in the asbestos industry, and received wages amounting to $1,350,000. In the Black Lake quarries, in the Province of Quebec, there are 451,000,000 tons of asbestos rock in sight. The Russians are the only real rivals as regards extent of asbestos resources, but are heavily handicapped by the excessive cost of transportation of $35 to $40 per ton from the Russian mines to London. Serious competition is not feared by the Canadian companies on this account.

The asbestos slate or shingle industry is being developed by the plants in Canada, and predictions are made that in a short time 75 per cent of all the asbestos produced in the Canadian quarries will be used for asbestos shingles. The asbestos-slate business is only five years old, but during that time the demand for this article has increased enormously, and large factories are being established to supply the demand for this new roofing material.

HOW TO SELECT DRAWING INSTRUMENTS.

Under this heading the Keuffel & Esser Co. are sending from their general office and factory at Hoboken, N. J., a dozen or more pages from their catalogue. The pamphlet describes in detail their grades of drawing instruments, especial attention being paid to the construction of the Pivot joint of their dividers and compasses.

Many architects and draftsmen are familiar with the Keuffel & Esser Co. goods, and others should inform themselves as soon as possible.

WARM, COOL AND QUIET DWELLINGS.

Under this appropriate heading the Union Fibre Co. of Winona, Wis., are sending out a fine catalogue describing their products and illustrating their use as applied to structures of many kinds.

Of course we want a house warm in winter, cool in summer and free at all times from internal vibration from room to room and from floor to floor. But the question is, how can these results be best obtained. The use of insulation makes a house warm in winter by preventing the cold winds from penetrating and preventing the heated air from escaping. Wrapping a blanket around a house keeps out the cold air, and keeps in the warmed air exactly on the same principles that we wear clothes. The saving resulting from the use of proper insulation, such as Linofelt, soon exceeds the cost of

the installation, besides the greater comfort obtained through its use. What is true in winter is also true in summer, the protective effect of the insulation keeps the warm air outside, and makes the interior cool and comfortable on the warmest days.

It would be impossible to build a tight wall thick enough to prevent any air passing through, but this might not prevent the changes in temperature or the passing of sounds and vibration, for instance if the partition was of sheet metal. By the use of a preparation such as Linofelt, the passage of heat and vibration are also stopped, making the walls and partitions practically sound proof, as well as guarding against changes in temperature.

Insulation should be used whenever it is desired: first, to guard a building against changes of temperature, keeping it warm in winter and cool in summer; second, to prevent sound passing from room to room or from floor to floor, as in schools, hospitals, conservatories, public halls, etc.; third, to keep cold places cold, as refrigerators, ice houses, cold storage, refrigerator cars, etc.; fourth, to prevent condensation of moisture on walls and ceilings.

Oak Doors Floors & Finish

at Less Than Dealers Ask For Pine

Despite the growing scarcity of Oak, which has been seized upon by lumber dealers and manufacturers as a pretext for raising prices on Oak Doors, Interior Finish and Flooring, we are actually selling the very finest qualities and grades at **less than dealers charge for Pine.** Years ago the Gordon-Van Tine Company arranged for the output of large tracts of the best Oak timber in America. **Our customers profit by our foresight.** We are actually selling Oak to carpenters and contractors at less than the same material would have cost you **ten years** ago. The cut in prices not only affects **Oak Doors,** but extends through the whole line of **Oak Finish and Interior Trim.** A further reason for our low prices on Oak is the big scale on which our goods are manufactured, and our small selling expense.

Oak Doors—All Styles

The most artistic line of Oak Doors in the country. Veneered Oak Doors set with French Polished Plate Glass; Craftsman Veneered Red Oak Doors, glazed in choice designs; Plain Veneered Oak Panel Doors; Oak Sliding Doors and many special designs, at less than half dealers' prices.

Inside Mouldings in "Mission" Styles

We carry in stock for immediate shipment, Oak Mouldings, Interior Finish, Beamed Ceiling, etc., to harmonize with any architectural scheme. Our prices save you big money.

Oak Flooring at Pine Prices

We are selling the finest grade of Oak Flooring at such low prices that you can floor a home in Oak at about the usual cost of Pine.

Our Millwork Catalog Your Savings Bank

We sell by mail direct to thousands of Carpenters and Contractors. Our Grand Free Millwork Catalog describes, illustrates and quotes net prices on over 5,000 Bargains in Building Material. We guarantee quality, safe delivery and satisfaction. We save our customers over a million dollars a year.

Protect Your Profits!

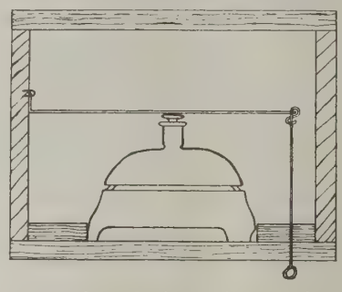
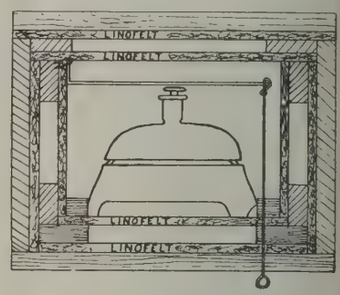
It ventilates the column, thereby preventing checking or opening and does not allow water to stand at the base to cause rot.



WRITE FOR CIRCULAR J



Syracuse Corner Block Factory

SYRACUSE, N. Y.

The city building, as well as the farmhouse, must be protected, the large schoolhouse in the city needs insulation no more than the barn or stable in the country. It is a well-known fact that cows will give more milk on less feed when kept in a warm barn. A garage must be kept warm to prevent the radiator from freezing, and it is almost impossible to start a motor when the gasoline is chilled.

The Union Fibre Co. of Winona, Wis., are manufacturing the insulating material known as Linofelt, particularly adapted to the work mentioned above. Linofelt is a quilt used for building purposes, composed of a filler of chemically treated flax fibres, quilted between two sheets of building paper. Waterproof paper, asbestos paper, and other coverings are furnished for particular uses. Linofelt is regularly finished in two styles, the first consists of rolls three feet wide containing two hundred square feet to the roll. For placing between studding, a special form is used either sixteen or

twenty-four inches wide, having the edges prepared for nailing or fastening to the studs, thus furnishing a substitute for back plaster.

To determine the efficiency of Linofelt for sound proofing, a well known architect who seldom takes things for granted, made the test boxes shown below.

Two small wooden boxes alike in every particular were constructed, both containing bells, the familiar kind which are sounded by striking buttons attached to the clappers. A lever with a wire extending through the bottom of the box provided means for ringing the bell. One box was made of wood only; the other lined inside with two layers of Linofelt tacked lightly to strips.

The bell in the box without Linofelt could be clearly heard when the wire was pulled, nearly as far as though the bell were unconfined. The bell in the second box could not be heard more than two feet distant.

Linofelt is kept in stock in all the large cities and the manufacturers, the Union Fibre Co. of Winona, Wis., will be glad to send any additional information regarding the use of their material. The catalogue mentioned above is well worth close study to anyone interested in making their homes more livable, as it shows how the material can be applied to both old and new buildings.

ECONOMICAL VENTILATION.

Pure air as conducive to health and happiness, needs no explanation. Even in spring and summer, rainy and cool days necessitate window closing to the discomfort of many homes, offices, stores and school houses.

The Ideal Manufacturing Co. of Erie, Pa., are making a simple, yet perfect ventilator, which has all the advantages of the large, cumbersome and costly devices previously on the market. It is handsome, easily installed, free from the defects of the ordinary ventilators, and is very effective in operation.

That the readers of the National Builder may be acquainted with this excellent ventilating device, the Ideal Manufacturing Co. is making a special price for June inquiries. It will be saving money to investigate.

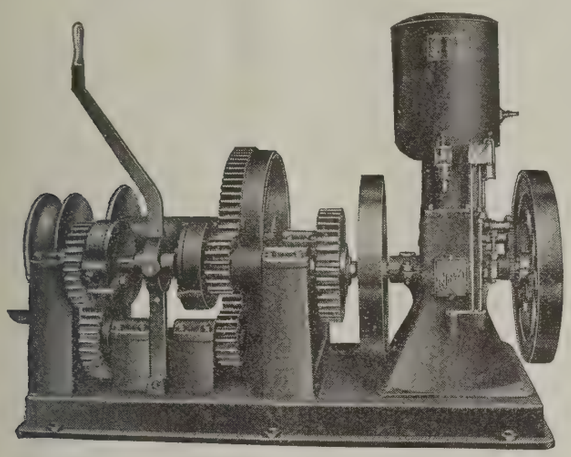
WOODWORKING MACHINERY.

No. 713 of The Mechanic, the house organ of the H. B. Smith Machine Company, Smithville, N. J., is of considerable interest to users of wood working machinery. Particular attention is shown in this number of their No. 107A extra heavy nine-inch outside molding machine. This machine is built for the heaviest work, planing 9 inches wide on material 12 inches thick. Many devices for accurate work and safety are found on this machine.

We understand that the H. B. Smith Machine Company will send this magazine free to interested parties.

NOVO ENGINES.

Scarcely a building is erected in which a pump is neither used during construction nor installed as a part of the permanent plant. During the construction there are springs sometimes met with, frequently a water main or sewer breaks and floods the excavation, and the use of a pump at such times alone frequently pays for itself many times over in the lives and property saved, as well as the saving in time during construction. Under the high-speed requirements of modern construction, handling the water is among the ordinary risks connected with the contract, and the contractor must be prepared for emergencies when a pump is the only solution.



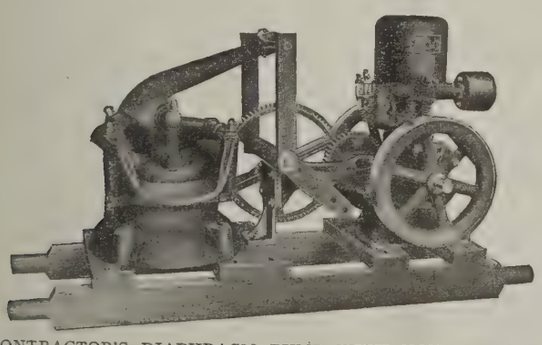
As the height of buildings increases, the contractor must provide means to get his material to the upper floors. Steam hoists have been tried, but the high speed necessary soon shakes the outfit to pieces. Electric hoists are ideal for many places, but the current cannot always be obtained. Gasoline hoists possess many advantages over other forms of power. Their horsepower is high for the weight of outfit, while their speed is high and adapted to intermittent use. When the contractor has a small shop it is imperative to have power for his machines. Most woodworking machinery is run at high speed, making gasoline power ideal. It is intermittent, for which work gasoline is on an equal with electricity and hours ahead of steam.

PASTE THIS DOME ON LETTERS THAT YOU WRITE ADVERTISERS. IT WILL HELP.

On the farm water must be provided for the stock and should e ready for extinguishing fires. The combustible nature of many arm products, such as hay, straw, grain, etc., renders some protection ecessary, but how often we see fine building destroyed when a few allons of water would save them.

These are among the emergency requirements, it is true, but they ust be met, and it is just as well to cut down the number of costly ossible emergencies.

But there is a new danger confronting the farmer which will ave a direct bearing on the high cost of living. The importation uring the last few years of injurious parasites, insects, moths, etc., lready costs this country millions of dollars annually. No one thing



No. 1 HOIST WITH 5 H. P. NOVO ENGINE.

an help the situation as much as spraying with the various prepara- ons known to be helpful. A proper pump for spraying is an invest- ent which will mean saving many times its cost every year.

The Hildreth Manufacturing Company of Lansing, Mich., claim at in the NOVO they have perfected the small gasoline engine. hree sizes only are made, from two and one-half to five horse power, nd by concentrating their efforts on these sizes they are able to roduce what they claim to be the simplest, most reliable and satis- actory engine on the market.

The NOVO is the result of years of study and experiment, based n sound, well-established principles, and combining the best features f modern practice. Space prevents more than a brief statement eyond the fact that the motor is built for hard, consistent and con- nuous work, on any of the work mentioned above, as well as running ream separators, pneumatic water systems, cement mixers, feed rinders, and all light farm and contracting machinery. The engine ove is self-contained, a complete power plant, ready to set up at ny time or place, and needing no pipe, tank or fittings.

One of the novel features of the construction of the NOVO is e manner of cooling. Only a small amount of water is used, oviating the necessity for tank or fan. The engine can be left out l winter without danger from the weather.

CONTRACTOR'S DIAPHRAGM PUMP WITH NOVO ENGINE.

For the purposes mentioned above the NOVO can be obtained the engine only or connected with any of the machines men- oned. For the common purposes, such as hoists, pumps, etc., the se is made in one piece, making the entire engine self-contained. or general use, such as contracting, the value of this feature in rtability is apparent. We are able to show two forms of this novel gine, and the manufacturers, the Hildreth Manufacturing Company, ansing, Mich., will be pleased to send their catalogue or other esired information upon request. Users of small power machines ould investigate this engine.

To Mark Tools

Coat the tools to be marked with a thin covering of wax, hard llow, or paraffine by warming the tool slightly and rubbing the ax over the surface until it melts. Allow it to cool and make the esired marks with a sharp instrument such as a scratch-awl or eedle point set in a handle. Now, pour on nitric acid, which ill quickly etch the desired design. As soon as the marks are deep ough, wash off the acid and warm the tool until the wax melts nd can be wiped off.

UTILITY WALL BOARD.

Wall board offers many advantages over other forms of lining and finishing buildings. While many of these are apparent to the readers of the NATIONAL BUILDER, there are some things about Utility Wall Board which appeal to special lines. The writer was looking over the latest catalogue of the Heppes Company while on a train. When the page showing a garage came up, a fellow passenger exclaimed: "That's just what I've been looking for. I want to line my garage, which is of sheet metal, and that is the first thing that looks like it would do the work." In a building of this character the heat of summer must be kept out as well as the cold of winter. It is in such places that Utility Wall Board is especially valuable.

In the stables and barns, as in the garage, wall board is of great value. Being windproof as well as waterproof, it adds greatly to the comfort of the live stock. Most especially, the harness, carriage and feed rooms should be lined for protection from dust and dirt.

But not alone in the stables, garages, and outbuildings is the board available. Every room in the house is better for a lining of this character. So many are the advantages that we can only refer to a few, leaving it to the practical readers of the NATIONAL BUILDER to find more ways in which to use this excellent material.

The billiard room has always been a place of interest to the builder. When the walls are plastered there is danger of damage from cues, chairs, etc. Wainscoting is expensive, while wall board takes the place of both, as it can be panelled to represent burlap or other finish, and its tough, fibrous composition renders damage extremely unlikely, and repairs easy.

Attic rooms usually have so many corners and angles that their finish is the despair of the plasterer, unless the arrises are covered to hide the crooked lines. The naturally plain surface of Utility Wall Board allows its use here to perfection, and a small amount of panelling gives an artistic finish to an otherwise unsightly room.

How many times we see the laundry tucked away in a corner of the basement where the rough walls and unfinished ceiling do not add comfort, if indeed they do not injure the clothes. An ideal laundry room built in the basement and lined with Utility Wall Board will please the women folks. When given two coats of oil paint, the walls are proof against steam and moisture.

Every room in the house has its use for Utility Wall Board. In the living room an artistic effect can easily be obtained by using Utility Wall Board for side walls and ceiling, with box ceiling beams and side wall panel strips stained with mission stain, the panels painted to harmonize with the finish of the woodwork. By stippling, a burlap effect can be obtained and, in fact, the decorator has the widest range in selecting the finish, as the board takes either oil or water colors readily.

For bedrooms, it is customary to fill the joints between the sheets with Utility Paste Filler, when it presents a perfectly smooth surface for painting or papering.

When we come to the bathroom, our preference is really for tile, isn't it? But when we learn the cost we decide we will find something cheaper. Utility Wall Board readily lends itself to sanitary finish, as an enamel finish can be easily applied, which will permit washing the walls as often as required. The peculiar composition of the board makes it efficient as a sound retarder, so that the noise of running water is seldom heard outside the bathroom.

Among the advantages of Utility Wall Board is its easy application. A novice can apply it over plaster or other finish, or can nail it directly to the studding. The variety of sizes in which it comes makes it possible to order sheets to cut to advantage, thus utilizing almost every square foot of it. Contrast this to the rubbish left by the plasterer. An ordinary workman applies the board much faster than a lather can prepare the walls for the plasterer, and the work is finished without the delay in time, the cost or annoyance due to the wet plaster.

To guide the intending purchaser, the Heppes Company, 4516 Fillmore St., Chicago, will send their complete catalogue relative to their products. Complete instructions for measuring are given, and it is well worth having this information on file.

FARM AND SHOP POWER PLANTS.

In this age of machinery every effort is being made in industrial lines to reduce the lines of labor of both man and beast. So much so, that the term "horsepower" is almost a misnomer and a quasi-mythical term handed down to us from the ages before mechanical power became a possibility. In factories, both large and small, little attention is paid to hand labor, and only the most delicate adjustments are left for the skill of the hand and eye of the trained workman.

In the smaller shops, there is still considerable dependence on hand methods, but here, too, the power machines are rapidly filling the place of hand and foot power machines.

On the farm mechanical methods are applied to many operations heretofore left to nature. Cream is separated from the milk as soon as milked, instead of allowing it to rise in the old fashioned way. Ice is made by machine when wanted, instead of being cut when the weather permitted. The reaper and harvester have taken the place of the scythe and sickle, even as the threshing machine replaces the threshing floor and the flail.

In arid and semi-arid districts, the crops are watered when they need it, thus supplementing the natural rainfall, and even replacing it entirely. Many districts blossom in almost tropical verdure under mechanical irrigation.

It is but natural, therefore, to seek the best power for use in these many places. Handwork is too slow and laborious, animals are not sufficient to do all the work, the steam engine is cumbersome and cannot be easily transplanted, besides requiring expert attendance all the time. Electric motors require current from outside sources, making the service costly, and so the mind naturally turns to the gasoline engine. This motive power possesses the qualities of portability, small weight for high power and speed, low cost of operation, always ready for instant use, adaptable for any purpose within the range of its power, and needs no expert engineer to operate it successfully.

Foremost among the manufacturers of gasoline engines for power on the farm and in the small shop; we find Schmidt Bros. Co

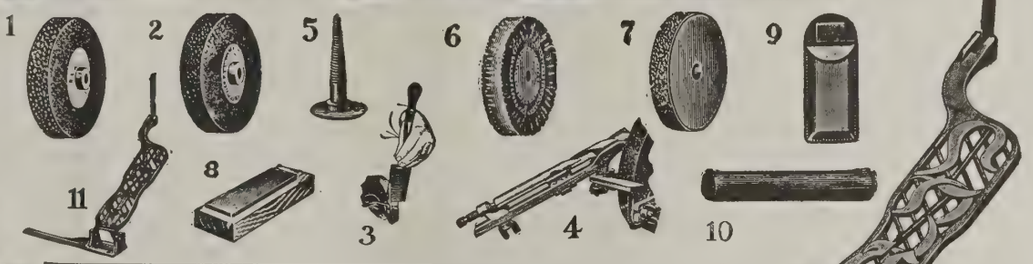
6 MONTHS FREE TRIAL

Special Offer on Shop and Factory Outfit

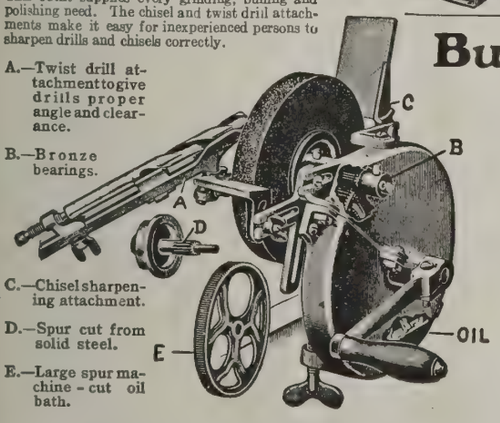
We want every carpenter, every shop, factory, contractor and tool-user to try this grinding, buffing and polishing outfit for six months free—a whole half year for you to find out how this perfected genuine Carborundum grinder saves tools, saves time, and earns money for any shop, factory or individual tool-user. We want you to prove these facts on your own tools. The whole half year's use will cost you nothing. Try it free for 6 months is what we ask and prove it is a big money-maker for you. Then send it back, if you wish—no hard feelings if you do. Send back the coupon at the bottom of this page for our 6 months' free trial offer.

Luther Diamond Tool Grinder



25 Times Faster Than The Grindstone—6 Times Faster Than Emery Wheels

The wheels of this grinder are genuine Carborundum. Nothing is so hard as Carborundum except the genuine diamond. Wheels actually made of genuine diamond would cut no faster. In reality Corborundum c ystals are artificial diamonds, made by fusing the elements of real diamonds in the electric furnaces at Niagara Falls, in which fire brick melts and runs like butter. In this *utmost* heat, Carborundum crystals get a temper and sharpness that cuts hardest steel or toughest malleable iron as emery does copper. Carborundum wheels do not glaze—they peel steel away in tiny shavings at lightest touch—no hard pressure necessary, no frictional heat, no water cooling necessary, no danger of drawing temper. Genuine Corborundum wheels do not get soft in spots, wear lopsided or glaze. They will outlast any number of emery wheels, saving that much money. They make it so easy to keep tools keen and bright, that tools are kept that way, and that means more, faster and easier work. They will not draw temper and tools last longer, which means another saving—to say nothing about the time saved in sharpening. But don't take our word—prove these facts by a half year's free use of this splendid outfit.



11 TOOLS IN ONE

This special offer on our shop and factory grinding, buffing and polishing outfit is a remarkable value—the greatest reasonably priced grinder offer ever made. This outfit, on which we will make a 6 months' free trial offer, consists of one Mechanic's Special Luther Diamond Tool Grinder with the following accessories;

1. One Rough Genuine Carborundum Wheel
2. One Fine Genuine Carborundum Wheel
3. One Chisel Grinding Attachment
4. One Twist Drill Attachment
5. One Polishing Spindle
6. One Buffer
7. One Polisher
8. One Oil Stone
9. One Carborundum hone in leather case
10. One Carborundum scythe stone
11. One foot power attachment

This outfit supplies every grinding, buffing and polishing need. The chisel and twist drill attachments make it easy for inexperienced persons to sharpen drills and chisels correctly.

A.—Twist drill attachment to give drills proper angle and clearance.

B.—Bronze bearings.

C.—Chisel sharpening attachment.

D.—Spur cut from solid steel.

E.—Large spur machine-cut oil bath.

Built Like a High Grade Lathe

The Luther Mechanic's Special, forming the basis of this Special shop and factory outfit, is built for a lifetime of service—has steel and malleable construction, dust-proof, bronze bearings, machine cut spur gears, bearings run in oil bath—speed 2,500 revolutions per minute. Carborundum wheels guaranteed 5 years.

Read what others say

Elmwood Haynes, of the Haynes Automobile Co., says: "I have found your machine a very satisfactory device."

Most Practical Grinder Made

I received the Carborundum Grinder and am highly satisfied with it. I consider it the best and most practical all-purpose machine so far manufactured.
ALLEN STOODLEY, Goldfield, Nevada.

The Best Grinder

I am well pleased with your grinder. It is the best grinder we have around here.
E. N. EARLES, Beallsville, Ohio.

What Neighbors Say

Your grinder does everything you claim for it and more too. I have shown it to my neighbors and they say it is one of the finest things they ever saw.
LEW KNUSTON, Leland, Ill.

Just As Represented

I have just received the grinder and find that it is just at represented. I am very well pleased with it.
C.H. THOMPSON, Cheyenne, Wyo.

Engine Works of Davenport, Iowa. In their latest catalogue and price list are shown many of the conditions when a motor of this character is well nigh indispensable. The novel points of construction make it especially valuable for places where the use is intermittent and where unskilled parties must operate it. The manufacturers claim that owing to its simplicity and reliability, this engine is particularly adapted to farm use for churning, separating, sawing wood, cutting fodder, etc., and can be easily rigged up to run a small woodworking shop.

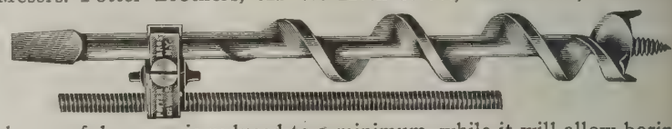
The catalogue is well illustrated and contains prices and the liberal terms on which the engine is sent for approval. On request from the readers of the NATIONAL BUILDER they will send the engine for ten days' trial before the first payment is made. But send for the catalogue and see for yourself how much labor can be saved by this little machine.

FRONT DOOR SET.

The Rehm Hardware Co., 1502 Blue Island Ave., Chicago, state that they are having quite a demand for their 5308 Front Door Set, which is shown here. The lock of this front door set has a cast bronze metal front, antique copper finish, 5-16 swivel spindle hub, bronze metal bolts and steel keys. The latch and dead bolt are operated by one key. The knobs and escutcheons are wrought bronze metal, antique copper finish.

Special attention is called to the fact that the night latch and the dead bolt are operated by one key. This is something quite new and will be greatly appreciated by the property owner. This front door set will add greatly to the fine appearance of any door or room. While the knobs and escutcheons of this set are wrought bronze metal, and everything else about it is of the highest class, yet the price is exceedingly reasonable

The Rehm Hardware Company will be glad to quote prices on either a few sets or a complete bill for builders' hardware for any residence or building. They carry a very large stock of fine builders' hardware, make prompt shipment and endeavor in every way to give their customers the best values for their money.



BURMITE ROOFING FOR IMPORTANT BUILDINGS

Bermingham & Seaman Company, with general offices at 1208 to 1226 Tribune building, Chicago, Ill., is meeting with a very gratifying demand for its Burmite material for roofing and siding, some of the most important buildings recently erected or under way in the northwest making use of this material as a roof covering. The utility of a high-grade prepared roofing for buildings of all kinds, and for roofs, whether flat or steep, appears to be well established. In addition to its cheapness, some of the advantages of a first-class rock-surfaced roofing are that it is not affected by climatic changes, nor by storms of wind, ice or hail, all of which are more or less destructive to roofs in general. Some of the important buildings roofed with "Burmite" include the Pioneer Press office building, a modern 18-story skyscraper which is regarded as one of the finest in St. Paul, Minn.; the warehouse of the W. J. Hoy Construction Company in the same city; the recently erected $250,000 St. Charles Hotel at Pierre, S. D.; the mammoth new lumber shed of the McMahon Lumber Company at Fergus Falls, Minn.; many of the depots of the Minneapolis, St. Paul & Sault Ste. Marie Railway; the warehouse of the Nicholas & Shepard Company at Fargo, N. D.; the new factory of the Towle Syrup & Refining Company, St. Paul, and many others.

THE PEERLESS FLEXIBLE BIT GAUGE.

When boring for mortise locks, dowels, etc., it is necessary to use great care not to bore too deep, as one unnecessary turn may strike a nail, cut through the stile or weaken the door. Many of the devices for gauging the depth of the hole are unreliable on account of springing, slipping or scraping, marring the work, etc. Others are limited in their range and will not permit of boring the full depth of the bit.

By the use of the Peerless Flexible Bit Gauge, the manufacturers, Messrs. Potter Brothers, 612 W. 110th street, New York, claim the

chance of damages is reduced to a minimum, while it will allow boring with any bit or twist drill to within three-quarters of an inch of the chuck of the brace. As there are so many places when this attachment, which can be put in any bit in an instant, can be used to advantage, every carpenter and woodworker should have one. While your dealer probably has the PEERLESS in stock, should there be any trouble finding it, write to the manufacturers at above address.

WOOD DISTILLATION.

The annual federal report on the statistics of forest production says that during the year 1909 there were consumed in the United States in the processes of wood distillation 1,256,157 cords of wood by 147 plants, as against 977,844 cords by 131 plants in 1908 and 1,282,120 cords in 1907 by the same number of plants.

The wood-distillation industry is concerned with the manufacture of such products as result from the heating of wood so as to produce volatile distillates and solid residue. Two distinct processes of manufacture, known, respectively, as the destructive process and the steam process, are in general use. In the former the wood is heated to such a temperature that the fibre is destroyed and new products are formed. In the latter the volatile substances are removed from the wood by treatment with steam, which does not destroy the fibre. Each process is modified to some extent for special uses.

The wood-distillation industry is naturally divided into two branches, "hardwood distillation" and "softwood distillation," and the statistics are presented separately for each class. With few exceptions, the establishments engaged in the former are confined to the Northern and Central states, chiefly Michigan, New York, and Pennsylvania, while the latter branch of the industry is located principally in the South Atlantic and Gulf states, especially Alabama, Florida, and Georgia.

Thirty-one establishments were reported as engaged in softwood distillation in 1909. Though the distribution according to states has changed greatly in the past three years, the total number is the same as in 1907 and only one more than in 1908.

Softwood distillation as an industry is still to some extent in an experimental stage. A number of the processes which have been tried have not proved uniformly satisfactory, and consequently estabishments have been abandoned or removed to more suitable localities. The total value of all the products of distillation amounted to $8,328,484, of which the value of charcoal was $3,509,019; wood alcohol, $2,082,253; other products, $2,637,212. These last products include tar, turpentine, oils, and pyroligenous acid.

The city of Yonkers, through its common council, has appropriated $10,000 for mural decorations in the council chamber of the new city hall, and in order to obtain these paintings the Honorable James T. Lennon has appointed as Art Commissioners, Rudolph Eickemeyer, Jr., G. Howard Chamberlain, and Charles H. Israels. For this purpose the Art Commission is instituting a public competition, for which competition a copy of the program may be obtained from the Art Commission of the city of Yonkers, care of James V. Mahoney, Board of Contract and Supply, City Hall, Yonkers, N. Y.

Amatite ROOFING

Why the Buyer of Amatite Never Complains

WHEN a man buys ordinary ready roofing he usually neglects to paint it and after three or four years he comes back to the dealer with a protest. It is human nature to neglect painting roofs.

When a man buys Amatite Roofing he lays it on his building and in three or four years it is still as good as new and does not need any paint. He forgets he has such a roof but no harm is done by that.

There is nothing to neglect in the case of Amatite. Amatite has a peculiar surface—a sort of plastic concrete made of pitch and mineral matter.

This surface is plastic enough so that the material can be rolled up into handy rolls in the usual manner and handled just like any other ready roofing. When unrolled on the roof and nailed down it presents to the weather a continuous surface of mineral matter and pitch. On this surface wind, rain, storm, heat and cold have little effect. Year after year it looks up to the sky undisturbed and unaffected. It costs nothing to maintain and relieves the owner from all responsibility.

Dealers can improve their business by selling Amatite and buyers make a good bargain when they buy it. The price of Amatite is less than that of most painted roofings of less weight and durability.

Sample free on request. Address our nearest office.

No Rubbing Needed for a Beautiful Flat Finish

Johnson's Flat Wood Finish, applied with a brush, produces the soft, velvety effect of the hand-rubbed finish at one-third the cost for labor. All that is necessary to obtain this beautiful flat finish on any woodwork, new or old, is to brush on a coat of Johnson's Flat Wood Finish. It dries in an hour without a suggestion of gloss.

Architects, contractors, Painters and Home Owners everywhere are enthusiastic over the results obtained with it and the big saving it makes possible.

Johnson's Flat Wood Finish

is a liquid—an easy spreading preparation—manufactured especially for finishing interior woodwork of new residences and buildings—as well as furniture—and equally valuable for refinishing old surfaces.

This flat wood finish opens a new field for the painter. He can now give his customers the beautiful, artistic, flat, hand-rubbed effects that have always been so high-priced on account of the labor—at prices that are within the reach of everyone.

By the use of Johnson's Flat Wood finish, you can make figures on hand-rubbed effects that will land the contract every time—give your customer perfect satisfaction and make you a good profit besides.

For giving this rubbed effect to new woodwork, apply Johnson's Flat Wood Finish over Wood Dye, Paste Wood Filler, or Varnish—for old woodwork or furniture having a gloss or varnish finish, simply apply a coat of Johnson's Flat Wood Finish. It is not necessary to remove the old finish before applying the new—and one coat *thoroughly brushed in* is sufficient.

Prices of Johnson's Flat Wood Finish

Gallons	$3.00
Half Gallons	1.60
Quarts	.85
Pints	.30

One Gallon is sufficient for 500 square feet

FREE Let us send you free a test can of Johnson's Flat Wood Finish and a copy of our Instruction Book. We want every painter—you—to know all about this most important development in wood finishing materials. We will send you a free sample so you may try it yourself at our expense and be convinced. Write today or fill out coupon for sample of Johnson's Flat Wood Finish and panels of wood finished with it.

Instruction Book

On Wood Finishing and Generous Samples FREE

To Painters

WE HAVE just gone to the expense of publishing a hand-book on Wood Finishing especially for our painters. This Instruction Book gives full information about finishing all wood—soft or hard—old or new. There is no point it does not cover. It tells you just how much material you will need for any work so that you can easily figure out your estimates.

We want a copy of this Instruction Book in the hands of every progressive painter. Write today for your copy which we are holding here for you. Remember we will send it absolutely free and postpaid. You are placed under no obligation whatever.

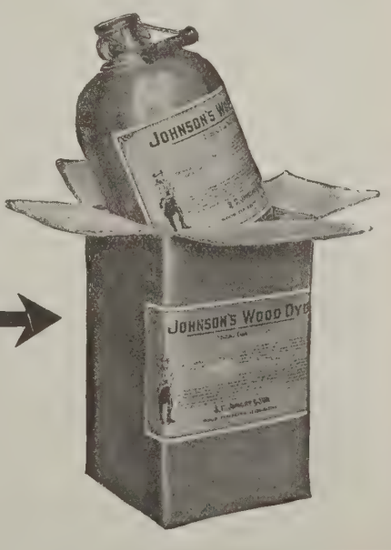
We will also send you FREE samples of JOHNSON'S WOOD FINISHES. After you have tried our brand we know that you will never use any other, for our wood finishes will ALWAYS give your clients satisfaction—you will never have a dissatisfied customer if you finish all of your work with "Johnson's" standard finishes.

Johnson's Wood Dye

is made in 15 popular shades as follows:

No. 126 Light Oak
No. 123 Dark Oak
No. 125 Mission Oak
No. 140 Early English or Manila Oak
No. 110 Bog Oak
No. 128 Light Mahogany
No. 129 Dark Mahogany
No. 130 Weathered Oak
No. 131 Brown Weathered Oak
No. 132 Green Weathered Oak
No. 121 Moss Green
No. 122 Forest Green
No. 172 Flemish Oak
No. 178 Brown Flemish Oak
No. 120 Fumed Oak

Gallons $3.00—Half Gallons $1.50



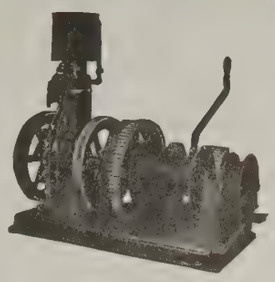
Johnson's Wood Dye penetrates deep into the wood fixing a deep, rich, permanent color which will not fade or rub off. It never raises the grain of the wood, and is very easy to apply, as it does not show laps and streaks even when used upon the softest woods.

Over the dye apply two coats of JOHNSON'S PREPARED WAX with a cloth and polish with a dry cloth or weighted brush. Prepared Wax gives that beautiful, lasting, artistic polish about which all of your customers are asking you.

GO TO YOUR LEADING PAINT DEALER for free samples of Johnson's Wood Dye and Prepared Wax. If your dealer hasn't the samples, write us for them, mentioning your dealer's name and the shade of dye of which you wish a sample and we will see that you are immediately supplied, free and postpaid.

S. C. Johnson & Son, [Dept. NB-6] Racine, Wis.

"The Wood Finishing Authorities"



We show here an illustration of our new gallon and half-gallon package of Wood Dye. Both sizes are packed in a carton which can be safely shipped by express to all points. This package is very easy to handle. Unused material may be kept absolutely airtight in it.

Be sure to write us for free samples and the INSTRUCTION BOOK if your dealer cannot supply you.

Screen Door

THE SENSIBLE SCREEN DOOR CATCH
A New Idea

The Sensible is the Catch that catches securely but quietly—prevents the door from warping, keeps out the flies, and reduces the noise of slamming to the minimum. Note the simple adjustment. Illustrations in this advertisement show catch one-third of actual size. Write for prices. Sample set mailed upon receipt of 25 cents.

Sears, Roebuck and Co.'s Great Lumber Mills and Yards at Mansfield, La., in the Heart of Americ

SUPPLY YOUR LUMBER NEEDS FROM TH

Why buy your lumber in dribs at high retail prices when you can buy from us in carload lots for the same prices or less than your retail dealer pays? A barn or building of ordinary size requires at least a carload of lumber

You Are Paying Too Much for Mill Work and Building Material

A Price Manual That Should Be on Every Builder's Desk.

"I would not take $5.00 for my Mill Work Book."

G. W. VAN-HOOSER, Dansville, N. Y.

IN THIS SPLENDID BOOK, the latest edition of which has just come from the press, we quote bed rock prices on more than 5,000 items. Our prices are not only the lowest, but our stock is also the largest and the best. You can buy the very latest designs in Craftsman doors and trim for about the same price which you pay for the ordinary doors in the local market. We can save you fully 50 per cent on magnificent massive buffets and china closets. Whether you are in need of $5.00 or $500.00 worth of mill work, you should have our new catalog in order to get the biggest possible value for your money.

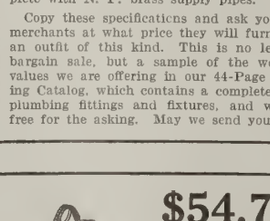
JUST GLANCE OVER THE FOLLOWING PRICES on a few items selected at random from our new Building Material and Mill Work Catalog:

$ 1.50 Doors	$ 0.95
2.00 Windows	1.10
1.00 Moldings, per 100 feet	.25
75.00 Stairs	22.80

WHY WE CAN QUOTE YOU THESE EXTREMELY LOW PRICES: The big mill work factory from which we ship your order carries a stock on hand at all times upward of **half a million dollars.** Manufacturing our material in such huge quantities enables us to control the raw material, and our big sales make it possible for us to operate with the smallest margin of profit. **You reap the benefit.**

DO YOU KNOW THAT THERE IS NOT A SINGLE STATE IN THE UNION INTO WHICH WE HAVE NOT SHIPPED OUR MILL WORK? Right in your own state are hundreds of people regularly doing business with us, and we will be glad to send you copies of unsolicited letters which they have written us telling of the good quality of our material, the big saving which we enable them to make, and the prompt and careful manner in which we ship the material.

Clip the coupon today, fill it in and mail it to us, or mention this magazine, and we will send you by return mail, postage prepaid, our great Building Material and Mill Work Catalog, which may be the means of saving you more than $1,000.00 during the present year.



Low Down Closet Combination, $12.25

Think of a low down combination, the tank of which is made of kiln dried oak with a beautiful golden gloss finish, capacity 6½ gallons, lined with 10-ounce copper, fitted with a combined lever ball cock, which is guaranteed to stand a pressure of 150 pounds, with a rubber ball valve, the most simple and serviceable valve on the market, and with china push button in front of the tank to operate it. The seat is made of the same grade oak and is furnished with cover, with heavy N. P. brass offset hinges. The bowl is made of the highest grade English vitreous ware, is a siphon wash down pattern, absolutely perfect in every way. Furnished complete with N. P. brass supply pipes.

Copy these specifications and ask your local merchants at what price they will furnish you an outfit of this kind. This is no leader or bargain sale, but a sample of the wonderful values we are offering in our 44-Page Plumbing Catalog, which contains a complete line of plumbing fittings and fixtures, and which is free for the asking. May we send you one?

$54.75

Ball Bearing Combination Rip, Crosscut and Band Saw Machine for Foot, Hand or Belt Power.

Other Machines $20.50 and up.

This machine has five ball bearing journals, one rip guide, one angle adjustable crosscut guide, one 10-inch rip saw, one 8-inch cut-off saw and one ⅝-inch band saw. Length, 15 feet. Ask for our Special Machinery Catalog.

We are independent lumber manufacturers. We control the raw material from which it is produced. Our price represents the actual cost of manufacture plus one small reasonable profit. We employ no middlemen.

How Can You Compete with another contractor builder or carpenter who buys his lumber from us at a saving of 25 per cent of the prices you have to pay a local dealer, unless you follow his example?

Your Success Must Depend (very soon if it does not already) upon your knowing where you can buy your lumber and building material and supplies at the lowest prices and to the best advantage. Such knowledge is worth as much to you as an understanding of any new method or feature of construction work.

A few items picked at random from o Lumber Price List, showing OUR PRICES our mill. Let us send you our DELIVERE WHOLESALE PRICE LIST, showing wh these and other items of lumber cost deliver in YOUR town.

1x4 Boards, 10 to 20-foot lengths. Pric per 1,000 feet board measure.

No. 1 grade	$13.
No. 2 grade	9.
No. 3 grade	$7.

Take Another Look at the illustration of ou great lumber yard. It is reproduced from an actua photograph, taken recently, and tells its own story Here we keep on hand constantly a stock of nearl 15,000,000 feet of dimension timber, ceiling, siding flooring, finishing and other lumber, soft pine, fl flooring, cedar shingles, cypress shingles, cypres lumber, pickets, lath, etc. We can fill your ever order, whether large or small, without delay an without substituting.

Remember that your purchase is loaded on th cars in this yard (and in the near future from ou Illinois yard) and unloaded at your freight depot You save all the expense of several unnecessar handlings, as well as two substantial profits—the jobber's and the retai dealer's.

Our Lumber Is Not Regraded. We guarantee all stock to run in eve width and thickness, and all tongue and groove material to be absolutel uniform. If you can use poor regraded stock on some of your work, wh not increase your profits by buying Southern mill grades from us and regrad ing the lumber yourself?

GET OUR PRICES ON ROOFING

We Can Save You $50.00 on the Average Size Roof.

A few of the remarkable values shown in our latest Roofing Catalog:

Tarred Felt Roofing.	Best quality, 108 square feet, 85-cent value. Price, per roll	$0.50
Rubber Asphalt Roofing.	The ordinary kind, 108 square feet, $1.25 value. Weight, 34 pounds. Price, per roll	.79
Flint Coated Rubber Roofing.	108 square feet, $1.65 value. Weight, 50 pounds. Price, per roll	.95

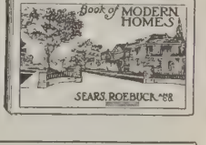
$1.10 to $1.23

a Gallon According to Quantity

Send for Color Samples and Catalog of Our Complete Line of Paints and Varnishes.

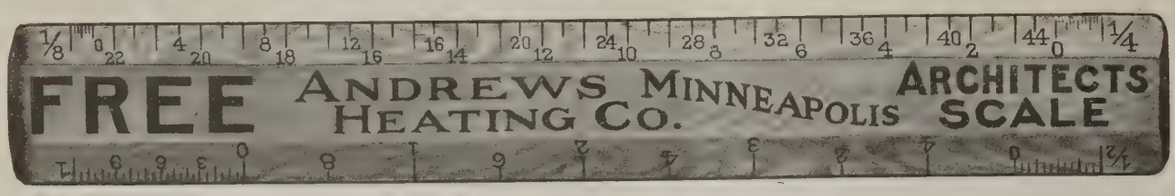
$1,050.00



FOR ONLY $1,050.00 we will furnish all of the material to build this large six-room frame house, brick, cement and plaster excepted. To give you an idea of the high grade material we specify, we direct your attention to just a few items as follows: Clear narrow bevel cypress siding, *A* cedar shingles, fir edge grain porch floors, clear oak and maple flooring and pure white tile flooring in the bathroom, Craftsman design oak doors, stairway and trim for the first floor, clear birch doors and trim for the second floor, a beautiful rustic fireplace with two colored glass windows on each side in the living room, and a massive oak buffet of the latest Craftsman design, with seats on each side, covering the entire end of the dining room.

$2,000.00 WILL NOT BUY YOU A BETTER AND MORE HIGH CLASS BILL OF MATERIALS IN YOUR LOCAL SOURCE OF SUPPLY. The difference between $1,050.00 and $2,000.00 represents your saving when you place an order with us for a complete house bill of the size and design illustrated above. We are enabled to make you this big saving because we are producers of lumber and sell the best mill work made at wholesale factory prices. We offer to sell you, Mr. Contractor, on the very same basis the local lumber dealer pays when dealing with his source of supply. You save the retailer's profit.

OUR BOOK OF MODERN HOMES illustrates, describes and prices nearly 100 houses for which we furnish all of the material at amounts ranging from $153.00 to $1,521.00. For each one of these houses we give complete building plans, typewritten specifications and an **itemized bill of materials** (our bid), placing at your command the best architectural service that can be procured.



TO PROVE TO YOU THAT OUR HOUSES ARE MASTERPIECES in design, substantial in construction, and can be built at an immense saving, we print in our Book of Modern Homes twenty-two photos of houses built according to our plans and with our material, together with letters from the builders telling of their experience. Thousands of dollars have been expended by us to make our Book of Modern Homes a really helpful building guide for contractors, carpenters and everybody interested in that line. You can't afford to be without it. Use the coupon today and ask us to send you a copy.

GASOLINE ENGINES

Equip Your Carpenter Shop with the Most Economical Power Known to Modern Science

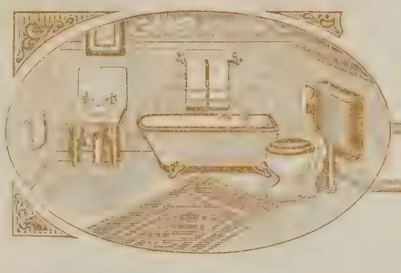
The latest and most modern types ever placed before the buying public. Economical both in *price* and *consumption* of fuel. Will produce more *horse power* for *every gallon of gasoline used* than any other Engines in the market today. Brand new direct from factory.

Price Wrecking Bargain 8 and 12 H. P. ENGINE only **$200** AND UP

We are willing to have our Superior Heavy Duty Gasoline Engines compared with any on the market no matter what the price. Built with the greatest care and every mechanical detail is carefully provided for. Best Engine for all around work on the farm and in the factory. Most popular Engine we handle, powerful and reliable, made for heavy work and continuous service. The 8 horse power is large enough for the ordinary work on the farm, also for elevators, factories, etc. The 12 horse power we recommend for small threshers, silo fodder cutters, etc.

30 Days' Free Trial AT OUR EXPENSE | **OUR GUARANTEE PROTECTS YOU**

Our two horse power "Superior" Engine is designed to meet the demand for a low priced Engine to take the place of Wind Mills, Hand, Foot or small Tread Power. The four horse power is designed for general farm or machine shop work.



The simplicity of construction makes them the most serviceable, easy to operate and Practical Gasoline Engine ever produced. We can recommend them with the utmost confidence to our patrons to give entire satisfaction.

They are just as convenient as any Electric Motor or Windmill would be for pumping water, running cream separator, washing machine or other labor saving devices in the house. It does not require any more practice or experience to run or keep these engines in order than the Motor or Windmill.

Two Famous Silver Steel Saws

We want to call particular attention to the two Saws shown in the pictures below. Both blades are of SILVER STEEL—both are Taper Ground—both are genuine ATKINS SILVER STEEL SAWS—BUT the handles are constructed on entirely different principles.

No. 53. Genuine Perfection Handle

No. 51. Old Style Handle

"Pay Your Money and Take Your Choice"

ATKINS No. 53

The picture to the left shows ATKINS No. 53 SILVER STEEL SAW equipped with ATKINS Genuine Perfection Handle and illustrates plainly why this type of handle is easiest on the saw arm. While it may feel strange to the beginner—a few days use will demonstrate that the Perfection Handle is the most *scientifically* constructed and much easier on the saw arm than any other style.

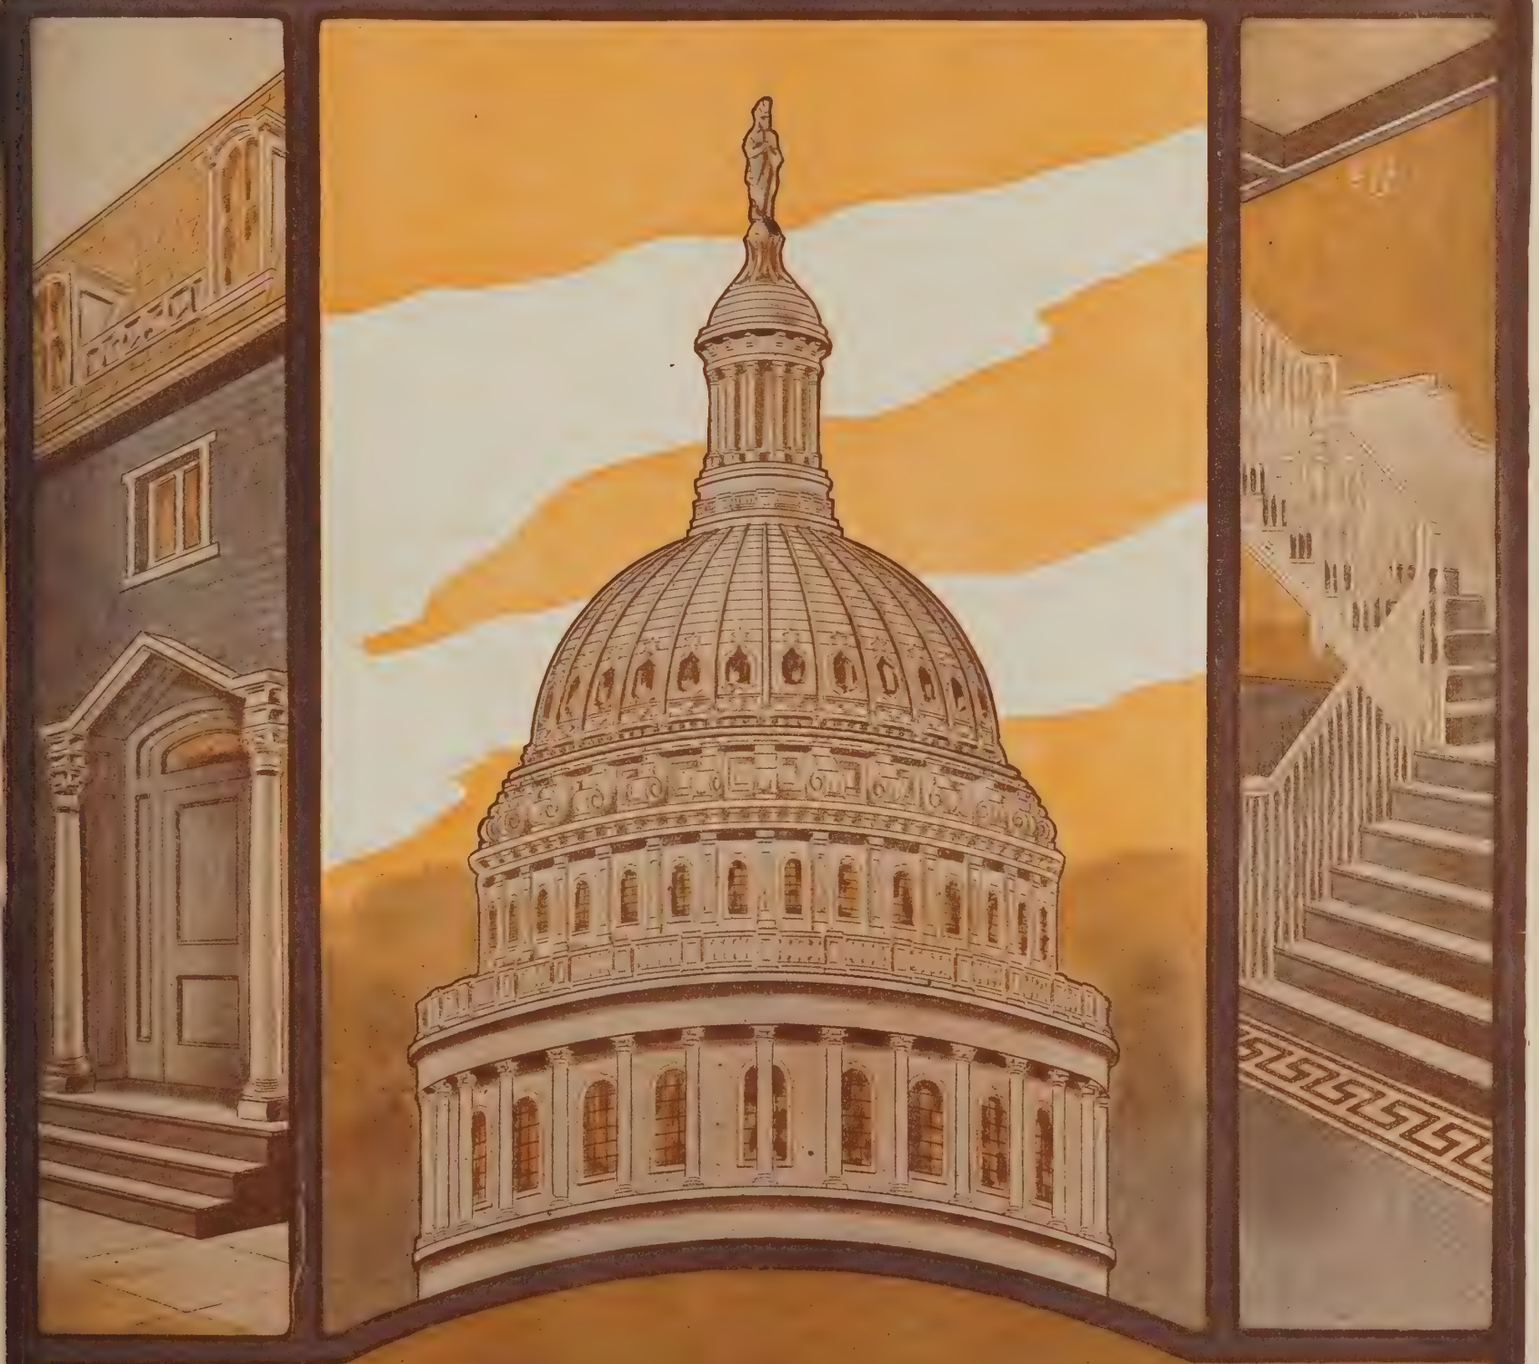
Note the line running through the saw arm straight through the blade to the cutting edge. See how every ounce of power is directed to the point of contact. Observe the wrist and saw arm, how easily and naturally the blade drops into its work without pressure.

ATKINS No. 51

If you are under the impression that all ATKINS SAWS are made with the Perfection Handle, we wish to particularly call your attention to the saw shown to the right. This handle is similar to the old straight across handle that you may have been using heretofore. Note the saw arm in this case and see that the pressure back of the saw arm is *not* directed on the cutting teeth, but rather to the back of the saw. Notice this wrist and see how it is necessary to push downward in order to secure proper contact. But even with this old style handle, the No. 51 is superior to any other, because the blade is made of genuine SILVER STEEL (our own exclusive formula) and is Taper Ground, which enables it to run free and easy, even in wet lumber, with but little set.

If you do not wish to try the Perfection Handle, then try the No. 51. Either of these saws or any of our other popular numbers may be purchased through your regular dealer, who should order for you from his wholesale house in case he does not carry them in stock. If he will not order for you, let us know and we will see that you are taken care of. Be sure to see that our name, E. C. ATKINS & COMPANY, and the words, "SILVER STEEL," are on the blade. None other are genuine.

OUR FREE OFFER



We are securing the names of high class mechanics who appreciate fine tools and if you will send us ten cents in stamps to pay postage, we will mail you one of our fine carpenter's nail aprons, Saw Sense Book, Time Book, and a great deal of useful information on the purchase and care of saws. Write today and learn "Who's Who" in the saw world.

Disston

SAWS
TOOLS
FILES

Economy goes hand in hand with increased efficiency when a Disston implement is introduced into factory, shop or structural work.

This is the day of close calculations in shop costs, and for this reason it is the day of the Disston Line just as in 1840.

Disston Saws, Tools and Files provide a trustworthy "helping-hand" to the experienced worker; lend confidence to the unskilled workman.

They reduce time and maintenance expense; they minimize errors in shop workmanship; they assure accuracy.

Before any implement is branded with a Disston trade mark it not only passes through many exclusively Disston processes, but after each operation a careful examination and thorough test is made—and then the final inspection.

A "Disston" overcomes the obstacles that defeat an ordinary tool.

BISHOPRIC WALL BOARD AND SHEATHING

ANY WEATHER is "Good Building Weather" when you use Bishopric Wall Board as a substitute for lath and plaster. It is cheaper and better and does away with all delays in building. It is nailed to studding dry, ready for immediate application of paper, paint, burlap, or any other kind of decoration.

FOR WALLS AND CEILINGS

Bishopric Wall Board Easily Applied

This substitute for lath and plaster is made of kiln-dried, dressed lath, imbedded in hot Asphalt Mastic, surfaced with sized cardboard and cut at the factory into 4x4 ft. sheets, which are easily and quickly nailed to studding, ready for immediate application of wall paper, paint, burlap, or other decoration.

It is applied dry, is guaranteed not to swell, shrink, warp, crack, flake or blister; is clean, sanitary, and odorless; is proof against moisture, cold, heat, and vermin; saves fuel in winter and keeps out summer heat; also deadens sound.

It is suitable for dwellings, factories, new partitions in old buildings, finishing attics, porches, laundries, cellar ceilings, garages, etc.

Applied Dry Winter or Summer

Shows Construction of Bishopric Wall Board.

PRICE WALL BOARD AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6.40 per crate, or $2.50 per 100 square feet, f. o. b. New Orleans, La., Cincinnati, or Alma, Mich. We ship from nearest point.

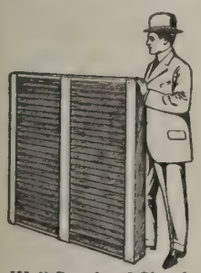
Cheaper Than Lumber. Saves 75% on Labor. Does away with Building Paper.

BISHOPRIC SHEATHING

Ideal Material for Cement Buildings or Stucco Exteriors. Proof against Dampness.

Bishopric Sheathing is made of same materials as Wall Board, but finish is not necessarily so fine, therefore costs less. It is of uniform thickness, insuring a perfectly even surface when applied.

Bishopric Sheathing is nailed to studs, with lath and asphalt side exposed. Over laths, weather boards are nailed or cement applied.



Shows construction of Bishopric Sheathing.

Arrow points to Asphalt Mastic into which laths are imbedded.

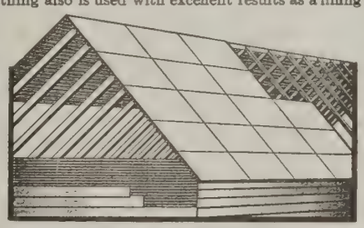
Bishopric Sheathing makes a more solid and substantial wall than lumber. There are no gaping joints; no widening cracks due to shrinkage; no knot holes.

The Asphalt Mastic in Bishopric Sheathing is a non-conductor, moisture cannot penetrate it. It is proof against vermin. The pests cannot bore through the tough, gummy Asphalt Mastic. In applying weather-boards over the laths, dead air space is left between the laths forming splendid insulation. Does away with the expense of building paper and cost of its application.

One Wagon load of Bishopric Sheathing covers an area from six to ten times as great as one load of lumber—a tremendous saving in hauling. Five thousand feet can be hauled in an ordinary wagon.

Wall Board and Sheathing are shipped in crates

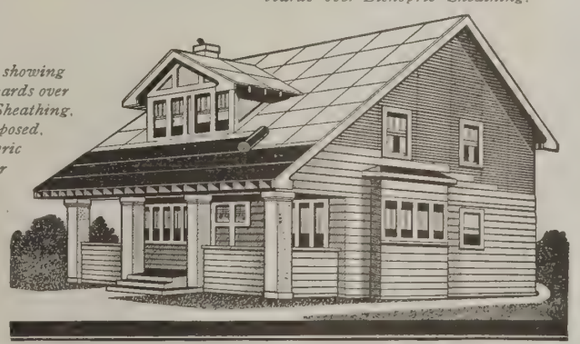
The cost of applying Bishopric Sheathing is but $2.50 per 1000 feet—A SAVING OF ABOUT 75 PER CENT. Furthermore, 1,000 square feet of wood sheathing covers but 750 feet of surface, 20% less being due to tongue and groove. In Bishopric Sheathing 1,000 square feet covers 1,000 square feet of space



In applying ordinary lumber, heavier scaffolding, more tools and greater scaffold floor-space are required In applying Bishopric Sheathing, one man drives a few nails in each sheet; a common laborer or boy can finish the nailing.

Bishopric Sheathing insures comfort during the construction of the building. As soon as the building is closed in with Bishopric Sheathing, the men may work in comfort on the inside during bad weather, finishing the outside on suitable days. This insures continuous work, without loss of time, enabling the contractor to hold his men and complete the work in the least possible time.

Bishopric Sheathing is used with equally splendid results under flooring and as a substitute for roofing boards. Used under floors, it serves as a sound deadener and keeps out dampness; used under the shingles, it keeps out summer heat.



ITS MANY USES—Bishopric Sheathing also is used with excellent results as a lining for dairy barns, ranch houses, poultry houses, driving stables or any out-door building where protection from the elements, Summer or Winter is desired.

Bishopric Sheathing is the ideal material for cement exterior or stucco work. Cement firmly adheres to the laths and Asphalt Mastic and makes a solid, smooth exterior. For factory or residence this form of cement or stucco construction is the cheapest and best known.

Shows Bishopric Sheathing over rafters ready for Bishopric Roofing, also Weather-boards over Bishopric Sheathing.

Ideal home showing Weather-boards over Bishopric Sheathing, lath side exposed, also Bishopric Roofing over Bishopric Sheathing. (smooth side of sheathing exposed)

PRICE SHEATHING AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6, or $2.35 per square of 100 square feet, f. o. b. New Orleans, La., Cincinnati or Alma, Mich. We ship from nearest point.

Write for Descriptive Booklet and Samples of Bishopric Wall Board, Bishopric Sheathing and Bishopric Roofing—All will be sent free.

Utility Wall Board

Is Used on Walls and Ceilings of These Artistic Rooms

The first illustration shows how easily Utility Wall Board can be applied. The other two illustrations show how nicely wall paper can be applied on walls and ceilings lined with Utility Wall Board.

Does it not look good to you?

Wouldn't you like to have us send you a sample of it—and tell you how economical it is—How easily it is applied—How artistically it can be decorated?

Our *beautiful illustrated booklet* tells the whole story—and shows pictures of artistic interiors. It is free for the asking, together with a sample of Utility Wall Board.

UTILITY WALL BOARD

is unlike any other Wall Board you have ever seen—It is made of exceedingly tough, durable fibre, thoroughly waterproofed—No moisture can penetrate it—It is applied directly to the studding, taking the place of both lath and plaster—Any carpenter can put it on—It will last as long as the house stands—You'll be amazed at the convenience of it—the economy of it—the beauty of it.

Mr. Contractor: This is your chance to make more money and finish your jobs quicker. UTILITY WALL BOARD is right in quality and price. It has come to stay and is rapidly taking the place of lath and plaster.

Every up-to-date contractor and builder should get samples of UTILITY WALL BOARD at once. There are hundreds of places it can be used with a profit to you and satisfaction to the owner.

Remember that all delays of the plasterer are a thing of the past for those who use this modern wall lining.

Don't fail to send for the sample and booklet at once—ask for our special proposition to contractors and builders

UTILITY WALL BOARD is Sold Through Dealers in Building Material Everywhere

THE HEPPES COMPANY

4502 Fillmore St., Chicago, Ill.

CompoBoard

THE MODERN WALL LINING

Better than Lath and Plaster in Every Way

Compo-Board will outlast lath and plaster several times over—in fact it will outlast the building itself.

Makes absolutely dry, warm, moisture proof walls and ceiling. Cannot crack, crumble or chip off like plaster. Keeps the rooms warm in winter and cool in summer.

Compo-Board can be used in any climate. It is quickly and cheaply put on in any kind of weather—no muss or dirt or waste of time waiting for plaster to dry.

Not only is Compo-Board a superior wall lining, but it has a multitude of uses in the home, around the yard, and in the office and factory.

Made of thoroughly seasoned kiln dried strips of lumber covered with a thick coat of cement and heavy durable paper put on under intense heat and pressure.

You can buy it in strips four feet wide and one to 18 feet long, any length you want in even feet.

SEND FOR BOOKLET AND SAMPLE

And you can see just what Compo-Board is, and read all about its many advantages and numerous uses.

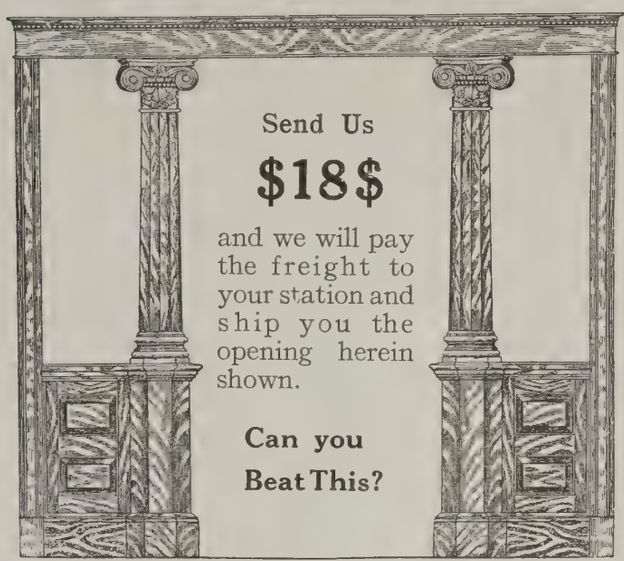
SAP GUM

Three years ago the architect or builder would have had a hard time to find any building of importance in which the owner had been courageous enough to use ***RED or SAP GUM.***

Today there are literally hundreds of apartment houses and fine residences in every section of the United States in which ***RED GUM*** has been deliberately chosen for the trim solely because of its actual beauty and entire practicability; and ***SAP GUM*** has also come into general favor for many builders' uses.

In places where White Enamel trim is required ***SAP GUM*** is the ideal material. Not only does it take and hold the white enamel better than any other wood, but it is possible to get good ***SAP GUM*** cheaper than any other wood hitherto used for White Enamel Woodwork. ***SAP GUM*** presents remarkable qualities where moderate priced trim of good appearance is desired. Another field in which ***SAP GUM*** has reached supremacy is in the manufacture of porch columns. ***SAP GUM*** takes stains and wood dyes beautifully, and the popular Flemish, Mission and Weathered Oak finishes are easily reproduced in ***SAP GUM.***



Anyone planning to build apartment houses, office buildings, hotels, residences or specially designed furniture, should defer final arrangements and correspond at once with any of the following firms regarding samples, prices and lists of important buildings of all types wherein RED and SAP GUM have been used with eminent practical success and signal artistic satisfaction.

BOOST YOUR OWN REPUTATION, MR. CONTRACTOR, BY TELLING YOUR CUSTOMERS—"PUT A STOP TO DEPRECIATION—BUILD WITH CYPRESS *AT FIRST*"

IS THE "LIFE-SAVER" of an HONEST CONTRACTOR'S REPUTATION

Here is a letter just received from a builder who **knows** by experience. Probably you feel the same way. Why not **CUT OUT TROUBLE?**

——— — ——— **Contractor and Builder,** — ——— **Street,**

PITTSBURG, PA., Mar. 22, 1911.

Southern Cypress Manufacturers' Association, New Orleans, La.

Gentlemen: Please send me information about Cypress lumber. Have about a dozen frame houses, from two to 16 years old, which I never get through repairing. Window frames, sash, siding, sills, etc., become rotten in a few years, and *the contractor gets a bad name* (as if it was his fault!)

Yours respectfully, ——— ———

This is a bona fide letter—"hot off the bat." The facts are all too true. HE WILL BE A CYPRESS MAN FOREVER. HOW ABOUT **YOU?**

We say it again—that by honest and intelligent advice on **woods** we are not only saving losses to people who are going to **build anyhow**—but we are also

CAUSING MORE PEOPLE TO BUILD

This is going to be of more and more benefit to **you** month by month. It is **up to you** to intelligently take advantage of this by **learning for yourself** that **CYPRESS** is not only the ONE BEST OUT-DOOR WOOD for the owner—but also the ONE BEST WOOD FOR **YOU.** Cypress **"makes good."** That helps your reputation. Cypress is easy to work—that's **good for your tools.**

We are giving away complete working plans and specifications for THIS SHINGLE HOUSE. Many thousands of people ALL OVER THE U. S. are writing for them. THEY WILL HAVE TO GET **YOU** TO DO THE WORK.

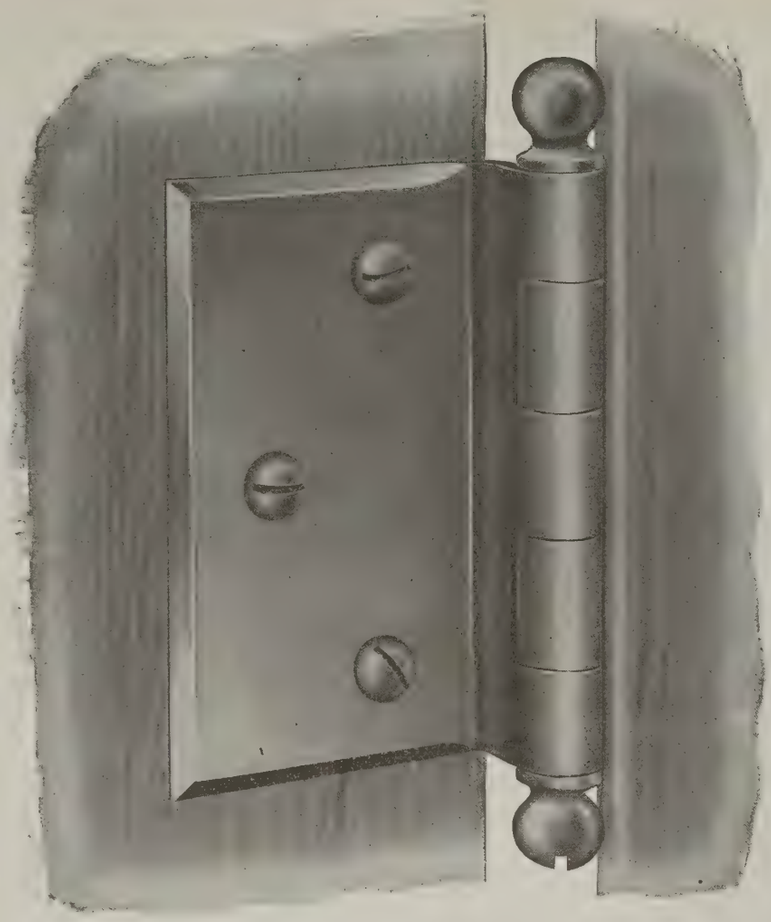
THEY WILL INSIST on CYPRESS.

It will be MONEY IN YOUR POCKET TO HELP THEM GET JUST WHAT THEY WANT.

CYPRESS

is the "comer" in YOUR territory.

LISTEN FOR IT



Why not FIND OUT what CYPRESS can do for YOU, NOW? WRITE US—ASK YOUR OWN QUESTIONS—about your own needs, big or little. You can rely on detailed and reliable **CYPRESS** information if you address our "BUILDERS' HELPS DEPT." We will recommend **CYPRESS ONLY FOR USES WHERE IT IS THE BEST WOOD TO USE.**

SOUTHERN CYPRESS MANUFACTURERS' ASSOCIATION

1212 HIBERNIA BANK BUILDING, NEW ORLEANS, LA.

We are *producing* CYPRESS—*and talking it—but not retailing it.* BUY IT NEAR HOME. *ASK your lumber man if he sells CYPRESS; if he does not, ask him WHY. Then WRITE US. We will tell you where you CAN get CYPRESS.*

NICHOLLS MFG. CO., OTTUMWA, IOWA

Go to the bottom of the roofing question—if you want to save money on your roof.

Don't be caught by mere looks and mysterious terms. Find out what the roofing is made of.

And the time to find out is before you buy—it is often costly to find out afterward.

Genasco

the Trinidad-Lake-Asphalt Roofing

is made of *natural* asphalt.

The difference between natural asphalt and manufactured or artificial "asphalts" is great. Natural Trinidad Lake asphalt contains natural oils which give it lasting life. They are sealed in Genasco and stay there to defend it permanently against rain, sun, wind, heat, and cold.

Artificial asphalts are residual products. Same way with coal tar. They are mixed with oils which make them pliable for a while, but the oils evaporate quickly when exposed to sun and air; they leave the roofing lifeless, and it cracks and leaks.

When you get Genasco you can be sure of roofing that lasts. And roofing that lasts is the only kind worth having.

The Kant-leak Kleet is the lasting waterproof fastening for seams—prevents nail-leaks, and does away with unsightly cement.

Ask your dealer for either Genasco mineral or smooth surface roofings with Kant-leak Kleets packed in the roll. Fully guaranteed. Write for The Good Roof Guide Book and samples.

Langdon Acme Mitre Box

These Mitre Boxes, when supplied with back saws fitted by ourselves, are warranted to give better service than any similar tool on the market.

There are a dozen improvements over the ordinary mitre box in the **LANGDON ACME** that insure quicker and more perfect work than any tool of its kind.

Some of the advantages over other models are: In longer guides, which hold the saw steadier, and these guides are provided with elevators to hold the saw stationary, when desired, above the work;

In a graduated arc showing the various angles commonly used;

In supporting guides, to hold the work in place;

In an appliance for quicker adjustment of extension lever;

In a length gauge for duplicate lengths.

There are other improvements—impossible to describe because of lack of space—which are explained in our catalog.

These boxes are made in three sizes and put up with varying sizes of saws, ranging from 22″x 4″ to 30″x 5″.

Send for the ***Free*** Book, "Tool Practice."

THE

"AMERICAN"

PORTABLE **SAW BENCH**

IS A CONTINUOUS MONEY-MAKER

This shows the Gasoline Engine Driven Style.

We can also furnish the "American" with Motor Drive for any current.

Some machine tools do good work—make money—at the outset. But they haven't the staying power which means permanent profit-paying capacity.

The "American" Portable Saw Bench isn't in this class at all. It is an "always-on-the-job" machine, ready for work at any time and doing good work all the time, year in and year out.

This peculiar distinction of the "American" Bench is the natural result of the care applied to its design and construction.

The best materials and plenty of them; strong, rigid frames; ample bearings; sturdy adjustments; ready manipulation; quick changes for various duties:—these are exclusive "American" features giving exclusively "American" results.

When you have finished one job with an "American" Bench, your machine is ready for another job. It asks no "lay-offs" after a spell of hard work.

An "American" Bench is a continuous money-maker. Send for the descriptive Bulletin and be convinced.

FAMOUS

You obtain all the woodworking machinery you need when you install the FAMOUS Universal Woodworker

Over six hundred progressive carpenters, builders and contractors are each getting as much service out of one machine as they could out of a complete machine shop. They use FAMOUS Universal Woodworkers.

Think of the time they save. Think of the labor they save. And think of the actual dollars they save. Then we are saying nothing about the added convenience they get.

You can do the same. You can have your own machine shop and be independent of planing mills. The investment is so small that you can easily afford one. But be certain it's a FAMOUS Universal Woodworker.

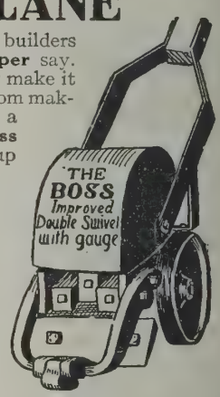
Acme Floor Surfacing, Laying & Finishing Co. Not Inc.

IT'S A SCRAPER BUT IT WORKS LIKE A PLANE



That is what the many satisfied contractors and builders who are using the **Boss Improved Floor Scraper** say.

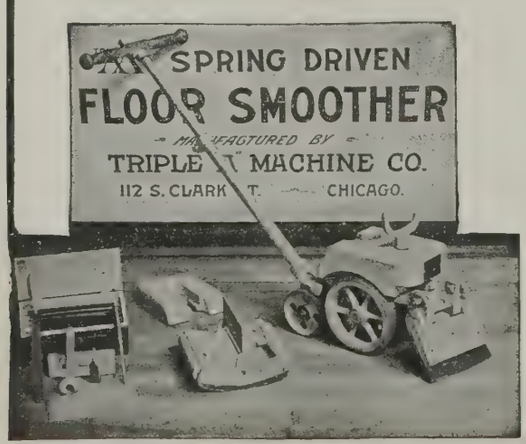
The **gauge** on the front and wheels at the rear make it like a plane. This gauge, which keeps the knife from making a depression in the floor, gives the knife a double support. It can be set for **any thickness of shaving,** or **instantly removed** for working up into corners.

Deep Cutting is prevented by the pear shaped wheel in front, which lets the knife down gradually to make the cut.

Poor work is **impossible** as with the simple but positive adjustment of this gauge and wheel attachment the knife leaves no mark. The standing attachment cleans the wheel and takes off the rosin when working hard pine.

Price very low. Write for descriptive Circular "N"

GEORGE J. KEPPLINGER, - Dwight, Illinois



When You Buy a Floor Surfacing Machine
BUY A GOOD ONE—IT PAYS!

The Triple "A" Spring-Driven Floor Smoother combines the advantages of the hand machine and the power machine. No more expense than the former, yet has the capacity and ease of operation of the latter.

No wasted energy pulling a dead weight.

About half of all the Triple "A"s sold have been bought by owners of dead weight machines. What's the answer?

"Get the best first and save extra expense."

The Triple "A" to be appreciated needs only to be seen in operation.

For advertising purposes we will give a special discount on the first machine sold in each town.

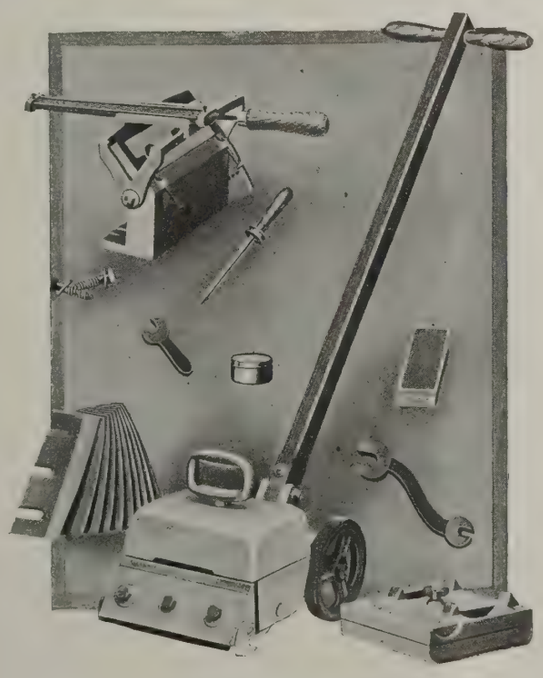
The WEBER DOUBLE ACTING Floor Scraper

The WEBER knives adjust to any desired slant for perfect work on all conditions of flooring. The WEBER is guaranteed not to chatter nor leave waves. The knife is held to its work—not by a dead weight—but by a flexible joint—similarly to action of human hand. The WEBER scrapes forward and backward. It has two knives, either of which can be brought into instant action. This rests you—saves your time—and enables you to scrape the centers of very small rooms. I guarantee perfect work in either direction. The saving in time and money in a year is a big item. The WEBER scrapes right up to the wall. By adjusting the handle to the right or left (see dotted lines), the extreme edge of the knife comes into direct draft with it. You can scrape right into the very angle of the floor without side draft, or marring the baseboard.

Try It Five Days FREE

Send for this scraper. Take it right out onto the job. Put it up against any other scraper made—on any kind of flooring. If its work isn't better in every way, return it.

Write Me Now



I also sell Wax Polishers, Saw Filing Vises, Cabinet Scrapers, Double-Folding Scaffold Brackets, etc.

Weber No. 1

This is my latest model. Note the handle adjustment, two knives, excellent balance, and workmanlike finish thruout. Made to save time and it *does* it.

661 71st Avenue - - - - WEST ALLIS, WIS.

A Trial Costs You Nothing

The Acme Floor Scraping Outfit.

By that I Mean

Absolutely Nothing

Sounds Strange—But It's a Fact

For many years I have been shipping the Acme Floor Scraping Outfit to interested parties on one week's free trial and if you have never taken advantage of this offer, you have been passing up a big money and labor saving proposition.

You don't have to take my word as to the "goodness" of my outfit. I give you the opportunity to prove it to yourself—more I cannot do. If you do floor scraping by hand you are wasting your money. I guarantee that the Acme Floor Scraping Outfit will do your floor scraping perfectly and to your entire satisfaction. Thousands of daily users are ready to testify as to its value to them.

Do you want full particulars of my absolutely free trial offer? Drop me a line and I will send them, as well as descriptive booklet by return mail.

An Easy House to Heat is a Cheap House to Own

An important question to the prospective builder or buyer of a dwelling is—"what will it cost to keep it comfortable?" The use of a sheathing material which actually prevents loss of heat through radiation and convection reduces coal bills and keeps a house warm in winter and cool in summer. Keystone Hair Insulator does this because it is made of cleansed and sterilized cattle hair, which, when felted together, offers greater resistance to the passage of heat and cold than any vegetable or mineral substance ever discovered.

Keystone Hair Insulator

is as much warmer in comparison with building paper as a woolen blanket is in comparison with a cotton (vegetable) sheet, **and for exactly the same reason.** Consisting of a sheet of hair felt between two sheets of strong, non-porous building paper, it is cushion-like in character and absorbs sound waves instead of conveying them. This makes it an effective sound deadener when placed between floors and walls. Get our booklet which shows how actual tests by big builders have proved Keystone's superiority.

The Original

BAY STATE Brick and Cement Coating

Protects concrete or stucco walls, floors and ceiling against damage from moisture and does not destroy the pleasing texture of concrete or stucco. It has been endorsed by the National Board of Fire Underwriters as a fire retarder, has been applied with great success to the exteriors and interiors of residences, hotels, factories and mills; when applied on ceilings it does not drop off, thus preventing damage to delicate machinery. It is not affected by acids or smoke.

FOR FLOORS

It prevents floors from dusting and sanding and is admirable for hospitals and similar institutions, will stand wear and washing. Write us for particulars about its application. We can give you the names of some of the best residences and best textile and other mills where it has been used successfully under most adverse conditions.

You Can Pay for the Mixer on a Single Job by the Greater Economy of Operation

It is not alone the saving of one-third in first cost, one-half in power, one man to operate the hoist and two-thirds the delays and repairs, but the greater portability enabling it to always be kept at the most convenient position on the job for rapid work, that are the distinguishing features of the

Eclipse Concrete Mixer

And we offer our patrons not only greater economy of operation, but unequalled service in shipment. We carry 100 Eclipse Mixers in stock at our factory, stores, warehouses and branch houses for immediate shipment.

It is pre-eminently the mixer for the contractor because it saves money in nearly every possible use.

Our new 1911 catalog No. 32 is just off the press and gives full information how to handle the Eclipse to obtain best results. Write for it. Our testimonial booklet explains how other contractors are making money by using the Eclipse Mixer.

You can buy the small size Eclipse Batch Mixer Complete with Power at a lower price than a Continuous Mixer.

–Forced Into Business by this Ideal Block Machine

Read Mr. Bradley's Interesting Letter

WYANET, ILL., MAY 29, 1911.

IDEAL CONCRETE MACHINERY COMPANY
South Bend, Ind.

DEAR SIRS:

I bought your block machine to build my own buildings, but my neighbors wouldn't let me stop there. I have made blocks for six other buildings, and they are begging for the blocks I have for my barn.

A man in Wyanet tried to make blocks with a ——— machine, but he had to quit—could not sell his blocks.

I am a farmer and cannot do justice to the business. Everyone that sees my blocks say they are the very best they ever saw, and I say so, too.

Yours truly,

(Signed) L. R. BRADLEY

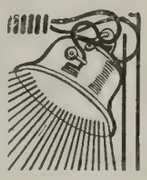
POLYGON "JUNIOR" MIXER

Specially designed for cement contractors whose requirements are met in a batch mixer of small size and low cost, that will turn out a perfectly mixed mass as rapidly and as economically as the larger machines.

Drum holds 6 cubic feet of loose material—turns out a perfectly mixed batch of 4 cubic feet. Mounted on steel skids or substantial trucks—with or without gasoline engine power. The Polygon "Junior" is one of



"THE GREAT POLYGON LINE"

including everything for the cement contractor—mixers of all sizes, power loaders, hoists, gasoline and steam engines, hand and power pumps, block and brick machines, trucks, sand and stone screens, culvert forms, dump carts and cement workers' tools. The Polygon line stands for satisfaction and economy.

Our Catalog illustrates and describes entire line.

"Northwestern"

"The Largest Line of Concrete Machinery in the World"

Northwestern Contractors' Power Batch Mixer

This machine combines all of the features which every contractor or concrete worker desires in a mixer. It has such a low intake that the material can be shoveled in from the ground or a small platform built and the material dumped right into the mixer with wheelbarrows. It has a high discharge and will empty into a wheelbarrow or into the forms. It is light and portable and can be readily moved from place to place. It has automatic watering tank and can be adjusted to discharge any given amount of water each batch. It will hold a full sack of cement with practically any mixture. It can be equipped with a power, stationary loader or low platform. We guarantee that this mixer will cost you $100 to $200 less than any standard mixing machine of equal capacity on the market.

Don't Fail to Send for Our Big Catalog

We manufacture everything in the concrete machinery line, including mixers of every style, size and description and we can furnish everything that you might need in the concrete line. Regardless of whether you are in the market or not you should have a copy of this catalog. Please state what you are interested in as we issue four (4) special catalogs. We are the largest manufacturers in the world and prepared to serve you with machines extremely low in price, simple in design and speedy in operation.

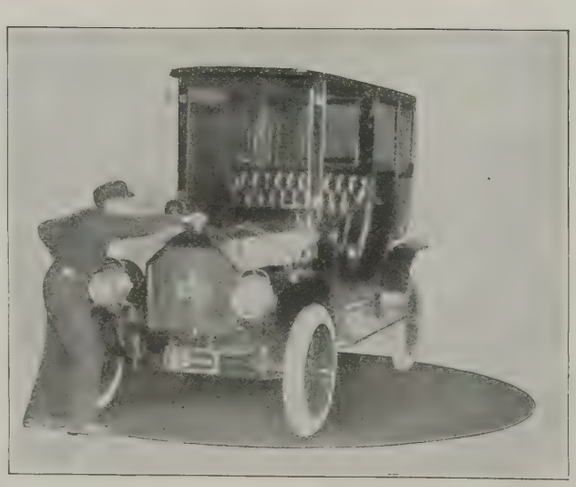
Sheet Metal Statuary of Rare Artistic Worth

WITHIN the last quarter of a century there have been reproduced at the Mullins Factory, Salem, Ohio, statues of Sheet Bronze and Copper that are nothing short of marvelous. Many of them were made from the models of famous sculptors, to their entire satisfaction.



We are prepared to reproduce, in minute detail, the most delicate lines of any model. It is this faithful portrayal which helps to account for the world-wide fame of Mullins Sheet Metal Statuary. Diana on the top of Madison Square Garden, the group on the New York Life Building, the Statue of Progress, Chicago, are among our earlier achievements.

We also make Fireproof Metal Windows, Skylights, Cornices, Finials, Metal Tile Roofing and Sheet Metal Ornamental Work of every description

Tell us what you're interested in and we'll send the proper catalogs at once. Estimates promptly submitted on architect's drawings. Attractive prices. Quick, satisfactory service. Discounts to the trade on application.

How Much Salary Are You Worth?

What can you do that any one of a million others could not do just as well? How much result-increasing or expense-decreasing knowledge can you bring to bear in your work? Have you any special ability? Is there any reason why an employer should single you out for more than average pay? Or are you just an average workman?

Look the facts in the face. "What can you do?" "How well can you do it?" "How much are you worth from your neck up?"—that's the line of talk Old Industry hands out to the candidate for prosperity. Are you ready with the answers?

If you knew the ins and outs of some trade or profession—if you knew the **why** as well as the **how**—you wouldn't have to ask for more pay. You'd just naturally get it. The **Help Wanted** columns of trade papers teem with appeals for trained men. Draftsmen are wanted; foremen are wanted; superintendents are wanted; machine designers are wanted; chemists are wanted; advertising men are wanted; electrical, civil, mechanical, and mining engineers are wanted; architects are wanted. Your salary will always be governed by the kind of work you are prepared to do. How much salary are you worth?

The business of the I. C. S. is to raise salaries. And the more than 400 voluntary letters sent to Scranton every month to tell of positions bettered and salaries increased through study of I. C. S. Courses prove how well the big institution is doing its work. No matter where you live, how insufficient your education, nor how small your means, the I. C. S. offer you a sure way to a better job. They have been increasing salaries for 20 years. They are doing it now. They are not going to stop.

It will cost you nothing but postage to find out all about the I. C. S. plan for making you worth more salary. Mark and mail the coupon. Doing it will place you under no obligation. Don't wait till tomorrow. Don't take chances on "put-it-offism."

MARK AND MAIL THE COUPON NOW

International Correspondence Schools
Box 1332, SCRANTON, PA.

Please explain, without further obligation on my part, how I can qualify for a higher salary and advancement to the position, trade, or profession before which I have marked X.

RAVENSWOOD MANOR, built at Chicago, Ill.

NATIONAL BUILDER DESIGN No. 343

L. E. Russell, Architect, Chicago

For Floor Plans, Elevations and Details, See Supplement Sheet of this number. Estimated Cost, $3,601.30

STIMATE OF RAVENSWOOD MANOR

y I. P. HICKS

EXCAVATING AND MASONRY.

130	yards excavating, 35c	$ 45.50
72	yards cement cellar floor, $50	36.00
17	lineal ft. chimneybreast, $2.50	42.50
15	lineal ft. chimney above breast, $2	30.00
300	cubic ft. concrete footing, 25c	75.00
9,000	brick laid in basement wall, $13	247.00
9,000	face brick in veneered wall, $25	225.00
120	yards stucco plastering, 80c	96.00
	Concrete front steps	15.00
	Stone caps	3.00
	Bolts for masonry	3.50
	Kitchen chimney	34.00
	Total excavating and masonry	$844.50
	lastering, 660 yards, 27c	$178.20

LUMBER BILL.

		Feet.
1,	6x8x20 ft. girder	80
1,	6x8x10 ft. girder	40
1,	6x6x14 ft. post	42
48,	2x10x24 ft. floor joists	1,920
10,	2x8x16 ft. wall plate	213
110,	2x4x20 ft. outside studs	1,467
24,	2x6x24 ft. ceiling joists	576
7,	2x8x16 ft. front porch	149
14,	2x8x12 ft. front porch	224
14,	2x8x10 ft. front porch	187
5,	2x8x16 ft. rear porch	107
2,	6x6x18 ft. rear porch	108
3,	2x12x22 ft. front porch	132
3,	2x12x18 ft. front porch	108
52,	2x6x16 ft. rafters	832
4,	2x6x20 ft. hip rafters	80
50,	2x6x18 ft. partitions	900

40, 2x4x18 ft. partitions	480
50, 2x4x16 ft. plates	533
20, 2x4x14 ft. dormer, etc	187
20, 1x4x12 ft. bridging	80
30, 1x6x12 ft. braces	180
20, 2x2x18 ft. furring	120
Total feet framing lumber	8,745
8,745 framing lumber at $27	$236.11
1,680 ft. 1x8, No. 2 boards, rough floor, $27	45.36
2,600 ft. 1x10, No. 2 boards, outside walls, $27	68.20
1,400 ft. 1x8, No. 2 boards, for roofs, $27	37.80
14 m. clear R. C. shingles, $4	60.00
8 rolls Neponset building paper	10.00
4 rolls red rosin building paper	3.00
200 lineal ft. 1x6, fir finish, $45	4.50
50 lineal ft. 1x4, fir finish, $45	.77
40 lineal ft. 1¼x12x16 ft., fir finish, $45	2.25
80 lineal ft. 1x8x16 ft., fir finish, $45	2.38
100 lineal ft. 1x12x16 ft., fir finish, $45	4.50
100 lineal ft. 1x12x16 ft., cypress finish, $45	4.50
240 ft. 1⅛x3x8 ft. clear cypress flooring for porch, $40	9.60
40 ft. 1⅛x3x6 ft., clear cypress flooring for porch at rear, $40	1.60
240 ft. ⅝x4 inch x 8 ft., beaded cypress ceiling, $30	7.20
40 ft. ⅝x4x6 ft., cypress ceiling, $30	1.20
64 2x2x16 ft., furring strips	9.50
1,720 ft. ⅞x2¼ face oak flooring, $80	137.60
140 ft. ⅞x2¼ face maple flooring, $60	8.40
600 ft. grounds, ½c	3.00
4 1¼x12x12 ft., fir finish	2.70
Total lumber bill	$660.17

MILL WORK.

1 cellar window frame, 16x20, 2 lt	$ 1.75
1 cellar window frame, 18x20, 2 lt	1.75
1 cellar window frame, 12x20, 2 lt	1.60
1 cellar window frame, 24x20, 1 lt	1.75
1 cellar sash, 16x20, 2 lt	1.50
1 cellar sash, 18x20, 2 lt	1.60
1 cellar sash, 12x20, 2 lt	1.40
1 cellar sash, 24x20, 1 lt	1.60
1 cellar door frame, 3 ft. 0 in. x 6 ft. 8 in	2.25
1 cellar door, 3 ft. 0 in. x 6 ft. 8 in. x 1¾ in	4.50
1 front door frame, 3 ft. 0 in. x 6 ft. 8 in., with side lights and transoms	10.00
1 O. S. door frame, 2 ft. 8 in. x 6 ft. 8 in., with transom	3.00
1 triple window frame, front	7.00
1 twin window frame, 26x16	4.50
1 twin dormer frame, 29x12	3.50
5 window frames, 28x30, $2.25	11.25
1 window frame, 28x18	2.00
1 sash frame, 38x18	2.00
1 sash frame, 28x16	2.00
1 sash frame, 28x16	1.80
1 sash frame, 24x16	1.80
3 window frames, 30x30, 2 lt., $2.25	6.75
2 windows, 19x30, 2 lt., $2.00	4.00
1 window, 12x16, 2 lt	1.75
2 windows, 26x16, 2 lt., $1.80	3.60
1 window, 30x36, 2 lt	2.60
2 side sash, 10x60, 1 lt., $2.00	4.00
5 windows, 28x30, 2 lt., $2.40	12.00
2 dormer sash, 24x12, 1 lt., 75c	1.75
1 window, 28x18, 2 lt	1.80
1 sash window, 38x18, 1 lt	1.60
1 window, 30x16, 2 lt	1.80
1 sash, 28x16	1.40
1 sash, 24x16	1.30
3 windows, 30x30, 2 lt., $2.50	7.50
2 windows, 14x30, 2 lt., $1.50	3.00
1 window, 12x16, 2 lt	1.25
2 windows, 26x16, 2 lt., $1.50	3.00
2 cased openings, col. and pedestals, $35	70.00
2 side lights for door, 12x52, $2	4.00
1 transom, 3 ft. 0 in. x 12 in. over all	2.00
2 transoms, 14x12 over all, 60c	1.20
1 rear transom, 2 ft. 8 in. x 12 over all	1.75
3 sets door jambs, 2 ft. 8 in. x 6 ft. 8 in., 90c	2.70
3 sets door jambs, 2 ft. 6 in. x 6 ft. 8 in., 90c	2.70
4 sets door jambs, 2 ft. 4 in. x 6 ft. 8 in., 80c	3.20
1 set door jambs, 2 ft. 2 in. x 6 ft. 8 in	.80
530 ft. base, cypress, 3c	15.90
530 ft. base mold, cypress, 1c	5.30
530 ft. floor mold, cypress, ½c	2.65
320 ft. cypress picture mold, 1½c	4.80
600 ft. 12 ft. cypress casing, 2c	12.00
240 ft. head casing, cypress, 2c	4.80
240 ft. cap mold, cypress, 2c	4.80
240 ft. fillet, cypress, ½c	1.20
100 ft. window stool, cypress 2c	2.00
100 ft. apron, cypress, 2c	2.00
320 ft. window stops, cypress, 1c	3.20
260 ft. door stops, cypress, 1½c	3.90
Front stairs	50.00
Sideboard	40.00
Medicine cabinet	6.00
Linen closet case	10.00
Mantel	30.00
140 ft. water table, 1½c	2.10
140 ft. bed mold, 1½c	2.10
100 ft. quarter round, ½c	.50
100 ft. cove, ½c	.50
3 porch newels, 50c	1.50
44 ft. bottom porch rail, 5c	2.20
44 ft. top porch rail, 5c	2.20
120 porch balusters, 4c	4.80
Total mill work	$430.20

CARPENTER LABOR.

8,745 ft. framing lumber, $9	$ 78.70
5,680 ft. sheathing, $8	45.44
14 M. red cedar shingles, $2.25	31.50
560 ft. porch floors and ceiling, $2	11.20
1,860 ft. finish floor, $2	37.20
1,600 ft. smoothing floors, $1.50	24.00
140 ft. cornice, 6c	8.40
50 ft. porch cornice, 15c	7.50
44 ft. porch rail and balusters, 30c	13.20
3 porch newels, 35c	1.05
2 porch columns, 60c	1.20
Rear porch steps	5.00
120 ft. belt course, 6c	7.20
Cellar stairs	8.00
Main stairs	24.00
Sideboard	16.00
Pantry work	15.00
Linen closet	6.00
3 closets, $1.50	4.50
2 cased openings, $6	12.00
4 cellar iron frames	6.00
1 cellar door	4.00
1 rear O. S. door	3.50
1 double-acting door	4.00
1 front door with side light	7.50
11 inside doors, $3	33.00
23 windows, $2	46.00
530 ft. base, 5c	461.09
320 ft. picture mold 1¼c	4.00
Work on dormer	10.00
Setting frames	10.00
Incidentals, 10 per cent	51.15
Total	$562.74

RECAPITULATION.

Excavating and masonry	$ 844.50
Lumber bill	660.17
Mill work	430.20
Carpenter labor	562.74
Hardware and nails	58.00
Tin work	56.00
Plastering	178.20
Plumbing	300.00
Heating	290.00
Electric wiring	50.00
Incidentals, 5 per cent.	171.49
Total estimate	$3,601.30

EDITORIAL NOTES AND COMMENTS

PERHAPS the biggest and most gorgeous function that ever took place in the world was the late coronation of King George V of Great Britain.

* * *

Eight tons of gold plate valued at $15,000,000, $100,000,000 worth of precious stones, and other tons of gold were carried about by kings, queens, noble lords and hereditary functionaries on their persons. This is foolery gone mad.

* * *

Displays of this kind, in these democratic days, in so democratic a country as England, seem very much out of place, out of tune, and out of time. Notwithstanding these "misfits" there must be something in their presence that tends to gratify, amuse and strengthen the patriotism of a great freedom loving people. Why?

* * *

A thousand years since the great Alfred cut the shackles of barbarism from off the fettered limbs of the early English, progress, enterprise, invention and the general advancement of mankind have grown, and thriven, in the motherland, and in the homes of her children, and it may be these great pageants, happening from time to time, have done much toward making the great events that gave us and perpetuated these blessings we now enjoy and appreciate so much. It does seem like a waste, the spending of so much money for these functions, but is it all a waste? A large portion of this money will find its way into the hands of the poor, both at home and abroad, and large sums will be distributed and set in circulation that likely would have been hoarded up for years had not the coronation and similar events forced it from the strong boxes of the rich. There are two sides to every question, and the shooting off of firecrackers and waving of bunting on each of our glorious Fourths, and a grand display of ceremonial trumpery, once in the lifetime of a crowned president, have much relationship, and have their uses for the public good. In England the king reigns, but the people rule; in these United States the people reign, but the politicians and trusts do most of the ruling.

* * *

Something worth while calling attention to in connection with the coronation, is the fact that it passed over successfully and was not marred by any serious accident. This is remarkable when we consider the number of miles of seating accommodation made and provided for the millions of people who witnessed the performances. For some days previous to coronation day alarmist reports as to the safety of the stands erected, the ability of the police to handle the crowds, and the condition of Westminster Abbey itself, were circulated, but few who knew how systematically and thoroughly such things are looked after by the London authorities were disturbed by such rumors. Not a stand gave way, not a limb broken, not a skull cracked, not a child injured, and everything went off in accordance with the prepared program, without a hitch; millions of people were handled as easily as though they had been trained soldiers. The credit of all this is not altogether due to the authorities; much is due to the good nature of the crowd, which, like all English speaking crowds, generally keep "heads level" and obey the law or rule that has been made in their interests.

* * *

Some of the wooden stands made and erected for the occasion were marvels in constructive art, and each one was built on the latest scientific principles, every piece of timber having been calculated to carry the load it was expected to sustain, and in which a large factor of safety was provided. Few nails were used, the most of the joints being held together by wrought iron bolts and rods or well proportioned mortise and tenon. Girders, trusses and braces were placed wherever such were required to give the frame stability and hold the structures from swaying laterally or across sectionally. Some 250 draftsmen and engineers were employed for several months previous to coronation day, designing and perfecting the plans for these stands, and not a timber or a plank was allowed to form part of the work that was not shown on the plans or was not examined and passed by an authorized inspector and marked with his official stamp. It is said that over 5,000 carpenters and other workmen were employed for weeks during the erection of these stands and that more people were hurt during the process of building than were injured during the entire coronation services; but during the whole period of construction and time of festivities, not a fatal accident occurred to any individual person taking part in them. If THE NATIONAL BUILDER can secure copies of the plans and details of some of the more noted of these stands, along with specifications, we will reproduce them for the benefit of such readers as may be interested in structural timber work.

* * *

Something less than a century ago there used to be a tax on building bricks in England, and in order to evade it the bricks were made of larger and larger sizes. These were used for cellars and other concealed places. To stop this fraud an act was passed in the reign of George III fixing the legal size of bricks. Early in Queen Victoria's reign the tax was taken off, and bricks may now be legally made of any size whatever. But any change from the standard would bring about great inconvenience. All calculations are made for building on this standard size, and the London building acts have practically fixed it at 9 by 4½ by 3 for all time.

* * *

It is said that the European notion of wall paper was imported from China. There its ornamental use for screens, partitions and the like was known as early as the fourth century. Authorities on this subject assert that it was Holland during her naval supremacy of the sixteenth century which first began to adopt and hand around the wall paper idea.

The early Chinese wall papers were printed from blocks, hand painted or stamped with infinite labor and exquisite art. They were made to order, produced in sheets of varying dimensions according to the uses to which they were put. The modern rolls of wall paper with a continuous duplicate design were unknown. It was not until the invention of the modern printing and stamping machines with cylindrical rollers that a continuous conventional pattern was favored.

* * *

As neither China nor Japan were a communicative country during the beginning of the commercial history of Europe, these wall paper exportations were few and far between and considerably at a premium. Yet they soon hit the European fancy as a good substitute for the arras and tapestries of the time.

Up to the end of the seventeenth century the imported product was prohibitive in price, however, and it was not until the middle of the eighteenth century that it was really a familiar thing on the market. When the methods for printing and stamping wall paper from blocks was introduced from China each nation was jealous of its neighbor in the wall paper trade and tried to keep its own process a secret.

Towards the end of the seventeenth century the English were the largest importers of the hand decorated Chinese wall papers, but only for a short time. As the demand increased they began to perfect a process of paper stamping and paper decoration to imitate tapestries, and with improved machinery soon cheapened their product and popularized it all over Europe. By the time of the Stuarts the arras of Shakespeare's era was beginning to disappear.

THE EMPLOYER AND HIS HELP

Much has been said in the various trade papers recently with reference to the proper methods to handle help. The writer has always assumed the position that employers and others in charge of help gain nothing by treating men like slaves and keeping them in constant fear.

The following article recently appeared in the Woodworker, as it voices the writer's views precisely, it is reproduced:

To substantiate this theory, the writer is able to cite a shop employing a good-sized force which is working under such an understanding at the present time. It is a fact that the lay workmen are not the only ones who would like to shirk the responsibility of mistakes in figures and management, for the foreman and superintendent may be in fear of the boss, as well as the others. But every owner and manager should know that the "super" is liable to more mistakes than any other one man engaged in the actual work of getting out the goods, especially if he is crowded with work and has to be his own foreman.

TIN ROOFS

By H. M. SANDERS

TIN PLATE in sheet form is not the same as in its pure state as an ore. As a metal pure and simple, it is of a brittle crystalline nature. It belongs to a class of soft metals, but not like lead or copper, sufficiently soft and malleable to be of practical value in sheet form without being alloyed with some other metal. To be of practical value as a sheet metal, it must be united to a harder and tougher metal; this harder and tougher metal, to be the body of the plate, and of a texture not too fine a grain, but sufficiently porous, so that the applied coating or plating of tin will penetrate beneath the surface and form a covering for the same, that will be lasting and not wash off by rains or weather exposure.

SIZE OF SHEETS.

There are some forty or more sizes of what is termed tin plate, varying in dimensions from 10x14 inches up to 42x96 and 120 inches in size. Of these forty sizes of tin plate while all of them are more or less useful and applied in the industry, those sizes that range from 10x14 up to 20x28 inches, are of the greatest commercial value, as they are the sizes most generally used.

The demand for the larger sizes above 20x28 inches in size has grown out of the necessities of the times, under the wonderful growth and development of the sheet metal industry during the past fifty years.

Tin plate is placed on the market packed in boxes. A box of 10x14-inch tin holds 224 sheets; 14x20 and 20x28-inch tin is packed in boxes holding 112 sheets each. As the sizes of sheets increase the number of sheets in a box become proportionately less. The idea is to have, as nearly as possible, a uniform weight in the handling of the tin in the boxes, upon each box thus packed is marked the size, thickness, and brand of the tin plate, usually at one end, where it can be seen when the boxes are stacked up.

In these later years, since there has been so much agitation, unfavorably and otherwise, over the subject of the quality of the tin now in use for roofing, manufacturers have been led to stamp on each sheet the brand and quality of the tin. The thickness of tin plate is designated thus: IC for the lightest grade, IX, one cross, the next heavier; IXX, two crosses, still heavier, and so on up until the highest grade, IXXXXXXX, seven crosses, is reached. The heavier grade above IXXXX are not in general use.

This latter plate, IXXXX, is placed on the market in sizes ranging in width from 36 to 42 inches and in length from 72 to 120 inches.

This idea of stamping each sheet with its quality and brand is comparatively a new thought, and not generally adopted until some twelve years ago, soon after the manufacture of tin plate in this country was started. Today this country has out-stripped England and become the largest manufacturers of tin plate in the world.

There are two classes of tin plate, termed bright tin and terne plate. The former is used mostly for all work except for roofing purposes. The latter, terne plate, is used almost wholly for roofing purposes and in most if not in all cases where the metal is subjected to outside weather exposure and climatic conditions. Before the introduction of terne plate, bright tin was used for roofing, as well as in all departments of the sheet metal industry, but for roofing purposes terne plate is considered better, as it is presumed to stand all kinds of atmospheric action upon it better than the bright tin. This is owing to the fact that the alloy with which it is coated or plated is composed of lead and tin, in the proportion of two-thirds lead to one-third pure tin.

QUALITY OF TIN PLATE.

The difference between a good and a poor quality of tin plate lies in the nature and character of its plated surface and in the fibral texture of the body plate which forms its base. But more largely in the latter, the fibral texture of its base, than in the composition of its outer surface, when considering its durability. The best quality of tin plate, both the bright tin and the terne or roofing plate, shows a bright surface on each side of the plate, free from specks or streaks. The bright tin plated wholly with pure tin has a bright polish of silvery hue. The terne plate coating, being two-thirds lead and one-third tin, presents more of a leaden hue, both sides of the sheet being covered with a smooth mottled surface. The body of the plate of the metal is soft and pliable, and of the best grade, free from pinholes or blemish of any kind, and sufficiently tough in its fibral texture to be worked into locked seams without cracking the body plate or its outside coating.

A skilled mechanic in sheet metal work can usually tell at a glance the quality of tin plate, whether it is a good or a poor quality, or rather, perhaps, it would be better to say, this was the case under the old conditions of the past, when the base of the tin plate was charcoal iron instead of sheet steel, so largely used today. This change in the base metal in tin plate, from charcoal iron to steel, has taken place within the past fifty years or since the introduction of Bessemer steel. For 300 years prior to that time no other metal but charcoal iron was used as the body plate of sheet tin.

Now the question arises, what has been the effect of this change in the base of this metal upon its value as a roofing material? It is true that some of our American manufacturers claim that it is better, others that it is equally as good. Hence we have the new old style brands. If this were all true as to fact, of what significance the tin plate conference, held in Baltimore a few years ago? This conference was called for by the National Association of Master Sheet Metal Workers of this country, and was held under its auspices in conjunction with the manufacturers of tin plate. Heretofore, and not until the introduction of the steel plate, such a conference was never known in this country before, or required. Nor as to fact, would this tin plate conference have been called had it not been that tin plate was losing its foothold as a material for roofing purposes. While perhaps the outcome of this conference was not wholly satisfactory as to results, it showed the trend of such a movement toward the betterment of conditions. But under present conditions, in an age of such revolutionizing tendencies as at present, it has become a serious question, as to how far the effort to reduce cost of production, under the pressure of the times of strong and sharp competition, is to depreciate the value of material. That this condition exists and that it has a deleterious influence and depressing effect on the use of tin plate for roofing purposes, is lamentably true.

It is a well known fact that prior to 1875 there was no such thing known as a steel base for tin plate in general use.

It is also an equally known fact that tin roofs began to deteriorate in value on the introduction of Bessemer steel base since that time.

Upon the cause of this deterioration, Mr. W. S. Goddard had this to say before the tin plate conference: "That while the cause of this trouble is a question as yet unsolved we know that it does exist and no remedy has yet been found. It is known to be what is called an internal corrosion, or disintegration of the steel base between the coatings. When this occurs the coating disappears and you have a pinhole or rust spot, for it is a well-known fact that the coating will not adhere to rust or when the surface is not perfectly clean.

Rust, or the hydrated oxide of iron, once established, contains all the elements of a long and ceaseless life, and as long as it is in contact with a ferric body its activity never ceases. It is to a terne plate what a cancer is to the human body. Rust begets rust. It may be held in check for a time, but when the efficacy of the material used to check it is exhausted, then the rust again commences its inroads. There is only one cure, and that is to eliminate every trace of rust."

So we can see the senselessness of the claim put forth by many, that a tin roof should be allowed to rust before being painted. Those who advocate this, simply start the rust on the way and defeat just what the mixture of lead and tin is applied to the plate for, namely, to preserve it from rust.

It is a well known fact that all the old reliable brands of tin made their enviable reputations as a roofing material on the fact that the base of the metal was charcoal iron. Examples of which in this country and in Canada, to say nothing of its use in England and other countries, show that these roofs have stood the test of seventy-five years or more.

Now in considering the relative value of iron and steel as a body plate for sheet tin, the question arises wherein lies the difference between them. The surface covering or plating in both cases are the same, and all other things being equal, their lasting qualities are the same. So, if one is better than the other for roofing purposes, we must look for the cause of it not in the character of the surface covering, but in the character of the metal which forms its base. The test in this matter is the comparative ability of the two metals to withstand weather exposure under all kinds of climatic conditions.

Iron has successfully met this test. Now as regards the use of steel let me quote what Mr. Goddard says about the character of steel:

"In coating steel sheets with tin and lead, the coating all lies on the surface, the plate absorbs none of it. This is because the molecules of the steel are small and lie close together, producing a fine, close grain with a surface admitting of a very high polish, while the molecules of iron are larger and more irregular, giving the plate a more open grain which can absorb to a more or less extent the coating of the tin and lead. Comparing the two metals to maple and oak: Maple has a fine grain and when varnish is applied it all lies on the surface, and is easily scraped off, leaving the surface of the wood as clean as a piece of glass, while the oak has to have its grain all filled up before the varnish is applied, and even after the varnish is scraped off the filling still remains for a protection. As an example, take a sheet of terne tin on a steel base and tack it fast to a board and with a sharp scraper scrape off all the coating; then rub it with a piece of fine emery cloth. Now apply a magnifying glass and you have nothing but a smooth, bright surface with no coating in sight.

"Treat a charcoal iron plate in the same manner, and then apply the glass and you find that the surface scraping does not remove the coating that lies beneath the surface, and that it is absorbed in the grain and molecules of the iron."

Hence the decline in the value of tin plate during the last quarter century of its use, with steel as its base plate, to one-tenth of its value in its lasting qualities as a roof material, compared with that of tin plate made with charcoal iron as its base metal.

METHODS OF LAYING TIN ROOFS.

The two kinds or classes of tin roofs are what are termed "flat seam" and "standing seam" roofs. The flat seam is used upon comparatively flat roofs, generally speaking where the roof pitch is less than 3 or 4 inches to the foot.

Sometimes, not often, we believe, 10x14-inch sheets are used, but generally speaking the 14x20-inch size tin is used. All flat seamed roofs are what is termed the locked roofs, put on one sheet at a time, in courses, each course breaking joints with the preceding course. Each of the sheets is cleated down to the roof with tin cleats, in size usually 1½x2 inches, usually three cleats to the sheet. These cleats are locked into the folded edge of the sheets, and the opposite end nailed to the roof. This gives free action for the expanding and contracting of the tin roof.

No nails should ever be permitted to pass through the body of the roof surface. Use resin or some flux without acid in it, when applying the solder. No acid of any kind should be used on a tin roof. It is needless to say—to the roofer at least—that after the tin is laid the seams are to be hammered down close with a mallet, before the process of soldering is commenced. After the roof is soldered, scrape off the resin, or flux, from the seams and sweep off the roof clean before painting it. After which, the sooner the better, paint the roof.

Flat seam roofs of 10x14 sheets require 8 pounds of solder to 102 square feet, and roofs laid with 14x20 size sheets 6 pounds to 100 square feet.

Now in regard to the laying what is termed a standing seam roof. Usually this class of tin roof is put together in 50-foot lengths, or rolls.

Sometimes 14-inch wide, using the 14x20-inch sheet, but generally speaking, for roofing purposes the 20x28-inch tin is used, making the width of the roll 20 inches wide.

Steep roofs of this character require but little soldering, and only in the cross seams. In making top and bottom connections on the roof the side standing seams are double locked and require no soldering, since the tin is put together in rolls of the required length to reach from the top to the bottom of the roof.

When each roll is unrolled on the roof, the side edges are turned up with the roofing tongs used for that purpose. The edge on one side is 1 inch high, and the edge on the other side of the roll 1½ inch high. These two edges, 1 inch and 1½ inches high, respectively, come together and form the seam, being double locked together. First, the 1-inch side of the roll is cleated down to the roof with a cleat with two prongs, one of the prongs to hold this 1-inch edge, and the other prong to hold the adjoining roll with its 1½-inch edge. The cleats are placed from 8 to 10 inches apart.

After the 1½-inch side is doubled over the 1-inch side, making a single lock, the top of the seam is again doubled over, leaving a seam about ½-inch high.

THE USE OF THE STEEL SQUARE

By J. H. B.

IN too many cases where a lean-to roof is used the top ends of the rafters simply lean against the wall, thus putting an immense thrust on the wall plate and the wall on which this rests. To obviate this thrust, and make the roof as near self-supporting as possible, the scantling A (Fig. 6) is nailed to the wall, the rafters being notched on to this, thus doing away with a great deal of the outward thrust, and the roof is made safe, or practically so.

In marking off the length of the rafter it is best to work from a line parallel with the backing, that is, the extreme edge of the wall plate, which means that a line must be drawn down the length of the rafter, at 1½ in. from the upper edge, as shown in Fig. 7. In setting out the length, it is necessary to remember that, while the width of the building is in no way altered by this, the height is reduced by about 2 in.; thus, instead of 7 ft. to work to there is 6 ft. 10 in. only. This means that the length of the rafter is found by working from the 12-in. mark on the long arm of the square and the 10¼-in. mark on the short arm, moving the square along the rafter as shown in Fig. 8 until it has been moved eight times, thus giving the width of the building: 8 ft. By this method the roof is practically divided into a series of parallelograms, as in Fig. 9, and by dividing the width into a certain number, and the required height into the same number, and working the square accordingly, any pitch can readily be obtained.

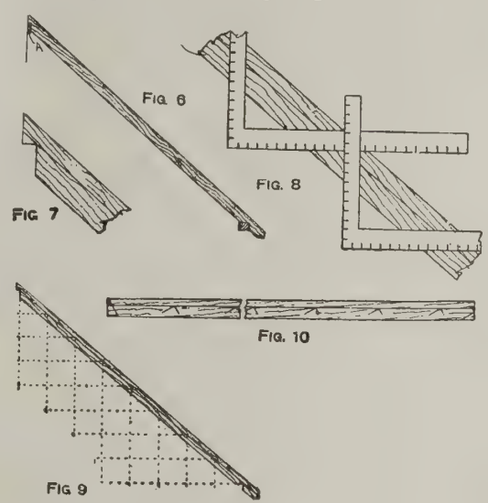

Fig. 6—Section of Lean-to Roof. Fig. 7—Top End of Rafter, Showing Backing Line. Fig. 8—Position of Square in Marking Off Rafter. Fig. 9—Principle of Marking Out Roof in Parallelogram. Fig. 10—Rafter as Marked.

As described so far, it is the marks on the square that have been used, and it will easily be understood that unless great care is taken mistakes are liable to be made. To do away with all chance of this as far as possible, it is best to use a gauge of some kind on the square, so that the latter is always kept at the desired angle. Then the only point to look after will be to keep it correct in shifting it along from mark to mark, as in Fig. 10, making all the marks intersect as the backing line.

Gauges for the above purpose can be purchased, and they are better than any home-made ones; but as expense is often an object, it may be mentioned that two strips of wood, screwed together with four screws, will do all that is required in this connection.

In setting the gauge, allowance must be made for the 1½ in. of backing, the points of the square worked to being brought to the backing line, when the gauge is resting against the back of the rafter.

In this article a roof of an even width has been chosen for the sake of simplicity; but in the next a simple span roof and odd inches will be dealt with. J. H. B.

HOW TO FIND THE LENGTH OF A BELT

The length of a belt may be found by adding the diameter of the two pulleys together and dividing the result by 2 and multiplying the quotient by 3¼. Add the product to twice the distance between the centers of the shaft and you will have the length of the belt required.

THE ART OF SILVERING MIRRORS

By A. ASHMAN KELLY

THE writer has received a great many letters from correspondents asking for information regarding the process for silvering mirrors, and some time ago there were several individuals who advertised their desire to teach the art, usually for two or three dollars. The "teaching" usually consisted of a formula or two for doing the work in some more or less undependable manner. While there is undoubtedly a large demand for information on this subject, mostly from painters who wish to add the work as a side line, yet it is far from being an art easily adapted to the inexperienced who wish to add to their income. Sometimes a mirror becomes damaged, and the owner wishes to know how he may repair it. As a rule it is cheapest to send it to a mirror factory. However, in the following article I will try to give plain directions for silvering mirrors, but must caution the novice that there are easier things to do successfully than this, and if he is disappointed in the result of his work, let him not worry nor blame anybody else.

Perfect cleanliness is the first thing to direct attention to. There are several formulas for silvering, some of which I give in this connection. One way is to lay the glass face down in the silvering solution; another is to pour the solution on the face of the glass, the law of capillary attraction keeping the fiuid from running beyond the edges of the glass, or if not, then press a little beeswax around the edges.

A second silvering, while the glass is still damp from the first coating, will make a better job than one coat.

The silvering may be protected by a coat of shellac varnish, over which apply a coat of japan black thinned with turpentine to the consistency of a paint. Or use asphaltum varnish. Some cheap mirrors are painted with red lead paint.

Silvering requires plenty of daylight and heated room.

Convex, concave, curved and chipped glass may be silvered, but such work requires more silver solution to the square foot than plain plate glass. Druggists' globes also may be silvered. There are also silvered mirror business signs.

At one time lead and mercury amalgam was used as a silvering solution, but as the materials were very poisonous they have been discarded.

To silver plate glass have a clean, warm room and a level and solid table to work on. Clean the glass with dilute nitric acid or with strong sal-soda water, and after washing this off, wipe dry and polish with tissue paper. Just any kind of plate glass will not answer for silvering, so be sure to ask for plate glass that is made for the purpose. Some of it is imported, but the best now is made in this country.

A Chicago workman gives the following formula for silvering:

No. 1 Solution: Take 80 grains of silver nitrate and dissolve in 10 ounces of distilled water; to this add 2 ounces of alcohol and 2 ounces of ammonia water. Add the ammonia drop by drop, until the precipitate first formed is dissolved. This should stand three or four hours before using it.

No. 2 Solution: Then take 6 ounces of water and dissolve in it 24 grams of silver nitrate, and add 30 grams of arsenate of copper. Now add liquid ammonia drop by drop until the first solution is dissolved. To this then add 2 ounces of alcohol.

Now make a separate solution of 48 grams of potassa in 16 ounces of water; bring this to a boiling point in a suitable vessel. While hot add solution No. 2, drop by drop, and continue boiling for about one hour; then allow it to cool, when it may be filtered and is then ready for use.

Place the glass on a perfectly level table as directed. Take some filtered water, just a little, and add to it equal part sof solutions 1 and 2; mix thoroughy; then pour it carefully over the glass, and as quickly as possible and when the glass has been covered level full, let it stand from 10 to 15 minutes. If, upon examination, the silvering is not brilliant enough, apply another coating of the silvering, while the first coating is still damp. When dry it is ready for the backing-up paint or varnish.

Seems simple, doesn't it?

Formula No. II. Make up No. 1 solution as follows: Dissolve 80 grains of nitrate of silver in 2 ounces of distilled water. Solution No. 2: Dissolve 80 grains of pure caustic potash in 2 ounces of distilled water. Add ammonia water drop by drop, with continual stirring, to solution No. 1. until the whole of the silver is deposited and redissolved. Then the solution will be quite clear. Now add the potash solution which will cause the first solution to become black. Add more ammonia water, drop by drop, stirring meanwhile. The slower the ammonia is added the finer the division of the silver. When the solution again becomes clear the action is complete. Now add a weak solution of silver nitrate, drop by drop, until a very pale brown color ensues. Errors may now be corrected by adding more silver or more ammonia, as the case may require. Silver should be slightly in excess in the first solution. THIS SOLUTION SHOULD NOT BE KEPT, AS IT IS A POWERFUL EXPLOSIVE. Filtering is not advised.

Now take 2¾ ounces of the solution and add water to make up 8 ounces. The glass in this case is to be placed in a bath, for which purpose have a suitable shallow vessel, say a tin pan of suitable size, coated on the inside with a mixture of equal parts of resin and beeswax, melted. On the bottom of the pan place two straight sticks ⅛ inch thick, on which the glass will rest, avoiding the bottom of the pan. Now pour on the solution carefully, avoiding air bubbles. Allow it to remain on a few minutes, then pour off the solution and add to it a 10 per cent reducing solution of grape sugar or sugar of milk.

This is then carefully poured back into the bath, over the glass, again avoiding air bubbles. The deposition of silver begins to take place, and the solution becomes muddy in color. The slower the action the harder the deposit. Leave until all of the silver is deposited, then pour off the solution and wash off the glass with distilled water several times. This washing with pure water is a very important part of the work, as when carelessly done brown spots will occur on the silvering in the future, spoiling the mirror. Dry the glass carefully, and be very careful not to mark the silver with the fingers, etc. Polish the face of glass with roughe. It is then done.

The room must be very warm, and hence perspiration is in evidence; if a drop of it gets onto the silvering it will spoil the job.

There are several methods or formulas, but the ones given here will answer all purposes.

RESILVERING A MIRROR. This is difficult, yet not impossible by any means. If the whole glass is to be done, then it will have to be made perfectly clean as directed for new glass, first removing the old material. But if only a portion of the old glass is to be remedied, then remove the silvering of the bad spot and a little outside and around it, and wash the spot clean with alcohol on a rag. Now from a piece of old or broken mirror take a piece of silver a little larger than the amount of the spot that is to be mended, and place on the piece a drop of mercury, and in a few minutes clear away the silvering from around the patch you are to transfer to the glass that is being repaired, and slide it carefully onto the latter. This is not easily done, yet with care and maybe more than one trial you will succeed in getting the patch onto the mirror.

The materials used in silvering will cost about a nickel for one foot of surface, and as the charge is usually about fifty cents a foot for such work it will all depend upon the time it requires to do a job as to whether there is a fortune in following such work or not.

The glass, whether old or new, must not have any scratches or other blemishes, for they will show up very plain when under or above the silvering. Precipitated chalk is better than whiting for polishing the glass with, as whiting is liable to contain grit. Dilute nitric acid is a good cleanser, with alcohol following, and a silk rag or tissue paper for cleaning up and polishing with.

GOVERNMENT WHITEWASH

Whitewash: To make the whitewash which has been used for more than thirty years in the White House at Washington and on the lighthouses maintained by the United States government along the coats, take a half-bushel of unslaked lime, slake it with boiling water, cover during the process to keep in steam; strain the liquid through a fine seive or strainer, and add to it a peck of salt, previously dissolved in warm water; three pounds of ground rice boiled to a thin paste and stirred in while hot; half a pound Spanish whiting and one pound of glue, previously dissolved by soaking in water, and then hanging over in a small pot hung in a larger one filled with water. Add five gallons of hot water to the mixture, stir well and let it stand for a few days covered. It should be applied hot, for which purpose it can be kept in a portable furnace.

LEAVES FROM A STUDENT'S NOTEBOOK—No. 2

By GEO. METSON

RIVETING RIVETED JOINTS.

IT IS first of all necessary to consider the size of the rivets to be used, in designing a riveted joint which should weaken the work the least possible, without employing an unnecessary amount of metal or time in making the joist.

The rough rules of rivets and riveting are briefly, that the diameter of the rivets used should be twice the thickness of the plates joined, if these last are less than ½ inch thick each. When the plates are half inch or over, the diameter of the rivet should be 1½ times the thickness of the plate. If the holes are drilled, the rivets may be slightly less in diameter than if they had been punched.

The shank of the rivet, i. e., the length before clenching from under the head, should be, of coarse, the total thickness of the plates to be joined, plus sufficient to clench, which may be taken as 1⅜ times the diameter of the rivet.

The usual dimensions of the heads of rivets are for the extreme diameter to be 1¾ times that of the shank, and the heighth to be 2-3 of the diameter of the shank.

"Pitch" of rivets means the distance from center to center of the rivets. The greatest pitch that should be used is 6 inches, as if placed at a greater distance there is a chance of moisture finding its way between the plates, which may cause rusting or corrosion, which may tend to force the plates apart. A rough rule is for the pitch to be twelve times the thickness of the plates in the joint, but a 4-inch pitch is a very common one in use for the compressional flanges of built up plates, girders, etc. The minimum pitch must be twice the diameter of the rivets used, but for practical purposes 2 inches may be considered the limit of closeness.

The distance from the edge of any bar or plate that a rivet can be placed is the diameter of the rivet.

The design of a riveted joint needs careful calculation. For an example, let it be required to find the size and disposition of the rivets of a bar having a lapped joint, the bar being required to withstand a pull of fifteen tons.

Without deducting for rivets, the bar would have to be

$$\frac{\text{15 tons pull}}{\text{6½ tons safe resistance to tension of steel}}$$

—say 2½ sq. in. in area, so that a bar 5x½ inch would suffice; but we must deduct 1-16 inch more than the diameter of the rivets used if the holes are drilled; or if the holes are punched, we must add 1-16 to each side of the actual diameter of the rivet. We will assume that the plates we propose to join are ½-inch thick, so that our rivets will be ¾-inch diameter.

We must next find how many rivets we require to make the joint. The calculations will be as follows:

Resistance to shear of one steel rivet is diameter² x 3.1416 x 5 = (⅜)² x 3.1416 x 5 = 2.2 tons, and therefore the number of rivets necessary to transmit the stress from one side of the joint to the other $= \frac{\text{15 tons pull}}{\text{2.2 safe resistance to shear of rivet}}$ = say 7, and these would be placed as shown in Fig. 1.

To further design the bar, we must employ the tentative method, i. e., assume a size and prove its correctness afterwards. Let us assume a bar 6½ x ½ inches. We will first see if the joint is strong enough across line XX. Here we have (6½ inches — 2x13-16 inches) x ½ inch x 6½ tons = 15.8 tons, which is sufficient.

Proceeding to test across the line YY, we have here for failure, for joint to break across this line and two rivets to shear. The calculation therefore is: (6½ inches — 3x13-16 inches) x ½ inch x 6½ tons + 2x2.2 tons = 17.6 tons. So the joint is strong enough all through.

There is, however, another stress to be taken into account, known as the "bearing stress of rivets," which should not exceed nine tons. The area of metal exposed to this stress is the diameter of each rivet in the joint multiplied by the thickness of the plate or plates against which they bear. In this case, we have ¾-inch rivets and ½-inch plate.

Area exposed to bearing given by each rivet = ¾x½ inch in our joint with a pull of 15 tons and with 7 rivets, the bearing stress per square inch $= \frac{15}{¾x½x7} = 5\ 5\text{-}7$ tons, which is well within the nine tons allowable. ¾

It may not always be possible to have a lapped joint, so we will now consider the same bar with a butt joint covered by a single cover plate as in Fig. 2. Here the load is transmitted from one bar to the cover plate and back to the other bar. The calculation will be as before, but it will be observed that the number of rivets in the joint are doubled. It is usual with single cover plates, to let them be thicker than the plates they join, and in some cases this will allow the length of the cover plate to be reduced. The cover plate here could be ⅝-inch thick.

If double cover plates are used, they need only be half the thickness of single cover plates. The rivets will be in double

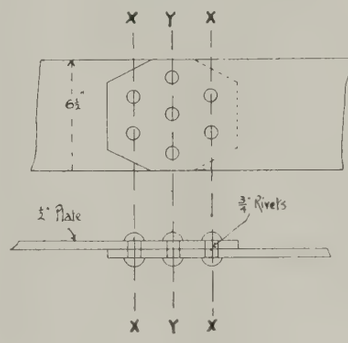

FIG. 1. LAPPED JOINT.

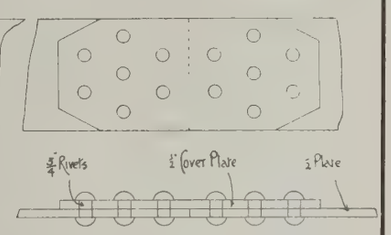

FIG. 2. SINGLE COVER PLATE JOINT.

STUDENTS NOTES ON RIVETED JOINTS IN PLATES.

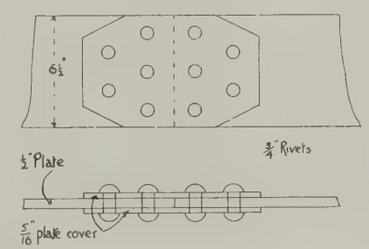

FIG. 3 DOUBLE COVER PLATE JOINT.

shear, each rivet offering resistance to shear between the bar and bottom cover plate, and also between the bar and top cover plate. But though this is so in theory, it is only usual to allow the strength of the rivets in double shear to be 1¾ times as strong as in single shear, and not twice as strong. So that with double cover plates, we can reckon on the safe resistance to shear of steel as being 8¾ tons per square inch. This will reduce the number of rivets required. These will now be $\frac{\text{15 tons pull}}{(⅜)^2 x 3.1416 x 8¾}$ (safe resistance to double shear of one rivet) = say four rivets. But before we complete the design we must look to the "bearing stress." Here it would $\frac{15}{¾x½"x4}$ = 10 tons, which is too much. We must, therefore, have 5 rivets in one joint as Fig. 3.

KINDLY MAIL CHECK

How dear to our heart is the steady subscriber
Who pays in advance at the birth of each year,
Who lays down the money and does it quite gladly,
And casts round the office a halo of cheer.
He never says, "Stop it; I cannot afford it,
I'm getting more magazines now than I read,"
But always says, "Send it; our people all like it—
In fact, we think it a help and a need."
How welcome his check when it reaches our sanctum,
How it makes our pulse throb; how it makes our hearts dance!
We outwardly thank him; we inwardly bless him—
The steady subscriber who pays in advance.—Ex.

PERFORMANCE OF BUILDING CONTRACTS

By W. J. STANTON

Where, by the terms of an entire contract, one is to build a house for another, within a given time and for a gross sum, he cannot recover anything until full performance on his part. In such cases performance is to precede payment and is the condition thereof; and the fact that the building is accidentally destroyed by fire or otherwise just before its completion, and without the fault of either party, does not change the rule. There can be no recovery before an acceptance of what has been done.

The same rule applies to a contract under which materials are to be furnished or put into a building where it is destroyed by fire, or otherwise, before the contract is fully performed. The loss falls upon the contractor and not upon the owner, for a contract to furnish materials and perform work in the construction of a building as an entirety, and no part of the work is regarded as being done, or material furnished, until the whole contract is complete.

A contract to build a house in which it is stipulated that the entire work is to be completed before any part of the compensation is demandable, is an entire contract. A workman can recover nothing under an entire contract for the building of a house which is destroyed by fire before its completion; but it is otherwise if the contract is not entire. A contract to erect a house for the cost of the labor and material, with a certain per cent of the total cost added as compensation to the contractors, payments to be made as the work progresses and the balance on completion, is entire, although there is no specific sum mentioned as the contract price. The payment of money by installments for the convenience of the contractor does not necessarily affect the entirety of his contract to build and deliver a complete house. Hence, if the building is destroyed by fire before completion, he cannot recover an installment not due him.

On the other hand if it is expressly provided in the contract that the last installment is not to be paid until the completion of the building, it cannot be recovered where the whole work is consumed by fire without apparent fault of either party, before its completion. In a California case the plaintiff agreed to repair an old house and to build a new addition thereto to be attached to it. The old house was to be turned, removed from its old foundation, and placed on a brick foundation, to be laid under both the old house and the new addition. There was nothing in the contract by which the price to be paid for any part of the work or materials could be distinguished from that to be paid for any other part. A provision in it that the third installment should be paid when the building was completed according to the agreement and specifications was construed as referring to the whole building, including the old part and the new addition, and the contract was therefore held to be an entirety.

A contract to erect a building for a certain price, payable in installments, is an entire contract and a destruction thereof by fault of the builder gives the owner a right to recover all installments paid. A latent defect in soil does not excuse a contractor from erecting a house which he has covenanted to build.

One party to a building contract cannot be compelled to accept work not performed according to the specifications, and to rely on recoupment for his indemnity. It is a good defense, in an action for work and labor done, in the building of a house on another's land, that the work was done in such negligent, unskillful and unworkmanlike manner as to be of little or no value to the owner of the premises. Upon the same principle, if the owner of a house and land agrees to sell and convey it, upon the payment of a certain price which the purchaser agrees to pay, and before full payment the house is destroyed by accidental fire, so that the vendor cannot perform the agreement on his part, he cannot recover or retain any part of the purchase money. Therefore, where the plaintiff contracted to sell and convey to defendant a farm having buildings thereon, and to deliver a deed in "fee simple of said premises" upon the payment, by defendant on a day named, of the price stipulated, and before the day named and the tender by the plaintiff of the deed, the buildings on the premises were burned, and the value of the premises greatly reduced thereby, it was held in Massachusetts that the plaintiff could not maintain an action upon the contract.

As exceptions to the rule that there can be no recovery upon a building contract until the work is done according to agreement, it may be stated that the general rule does not apply where unfinished work has been accepted, or has been used by, and is of benefit to one of the parties, and that a recovery may be had upon a divisible contract. Thus, if the owner clearly accepts the property when nearly, but not entirely completed, any loss occurring thereafter must fall upon him. Where the owner has accepted the building in its approximately completed condition, and is using it for the objects for which it was built. the law implies a promise on his part to pay what the work done is reasonably worth.

The question of acceptance, however, is a very delicate one. The mere fact of an owner's taking possession of his own land upon which buildings have been erected, or where repairs have been done or alterations made to a building thereon, does not afford an inference that he has dispensed with the conditions of a special agreement under which they were built, or of a contract to pay for the work actually done according to measure and value. A builder cannot recover unless he has complied with his contract, and it is held in New York that this is true, although the defendant has taken possession of and uses the building, as this is not necessarily a waiver of failure to comply with the conditions of the contract.

In a Massachusetts case there was a contract to repair a house and outbuildings for a certain sum, but when the repairs on the house were nearly completed the owner, by his tenant, entered and occupied it, after which the house and outbuildings were destroyed by fire. In an action for work done and materials furnished, the workman was held entitled to recover for the repairs done on the house when the owner took possession. The court recognized the rule that one cannot recover on a contract to do an entire piece of work for a specific sum unless the work is done, and therefore carefully stated that "the precise ground on which the plaintiff can recover in this case is, that when the repairs upon the house were substantially done, and before the fire, the defendant, by his tenant, entered into and occupied it, and so used and enjoyed the labor and materials of the plaintiff; and that such use and enjoyment were a severance of the contract, and an acceptance, pro tanto, by the defendant." To entitle a party to recover for part performance, or for performance in a different way from that contracted for, his contract remaining open and unperformed, it is sometimes held that the circumstances must be such that a new contract may be implied from the conduct of the parties to pay a compensation for the partial, or substituted performance, as the mere fact of partial performance being beneficial to a party is not enough from which to imply a promise to pay for it. Consequently it is held that if a builder fails to complete his contract to erect a house on another's land, or does not make the work substantially conform to the contract, the mere fact that the building remains on the land, and that the owner enjoys its benefits, he having no option to reject it, is not such an acceptance as will imply a promise to pay for it, in face of the fact that the special contract has not been performed.

As an exception to the general rule above stated, there have been cases allowing a recovery upon a building contract where it is divisible. If such a contract provides that the whole building shall be constructed for a certain sum, a specified portion of that sum to be paid upon the completion of the foundation walls, a second specified portion when the roof is on, a third specified portion when the plastering is completed, and the remainder when the house is completed, such payments are distinct and separate, and may be sued for as they mature. A building contract which is not an absolute one to do work at all hazards, but is dependent upon assumed and implied conditions which the other party is to perform but does not perform, is severable to the extent that a mechanic may recover for work done up to the time that the building is destroyed by fire.

If performance of a building contract is prevented by acts of the other party, the contractor is entitled of course to recover the reasonable value of the work performed and materials furnished.

The doctrine that there can be no recovery on an entire building contract until the work is done, is not the law of Texas. It has been held there that under a contract to furnish materials and perform labor in altering an existing structure, according to agreed specifications, with no provision as to time of payment, if the structure is destroyed by fire, without the fault of either party, when the work has been only partly performed, the builder may

recover for the work done. This case is opposed to the great weight of authority. The rule is just and founded in reason, for if he does not intend to bear the loss it is natural to presume that he will stipulate against it. The well recognized principle that, where one of two innocent persons must bear a loss, the law casts the burden upon the party who agreed to sustain it, or rather leaves it where the parties, by their agreement placed it, applies in such cases.

RECENT COURT DECISIONS

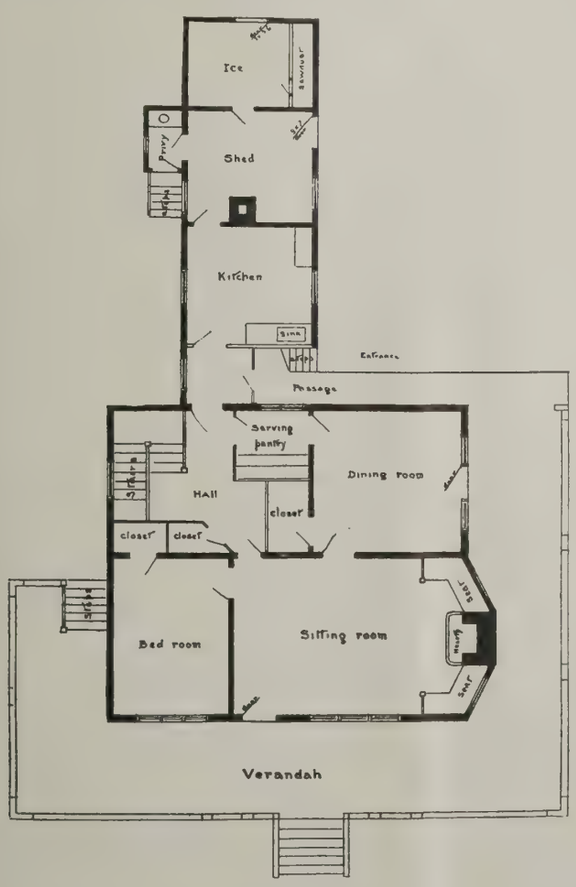
The New York Code of Civil Procedure, section 3414, makes a laborer's or materialman's lien prior to a contractor's. Section 2 of the Lien Law defines a "Contractor" as one who contracts with the owner of the land to improve it, a "Materialman" as one, other than a contractor, who furnishes material for such improvement, and an "Improvement" as including work done or property or "materials furnished for its permanent improvement." The New York Court of Appeals holds that the lien of one who installs plumbing, of one who furnishes trim for the building under contract with the owner, and one who sells brick and mason's building materials to the owner for use in the building, are all on an equality, being entitled to preference in order of time.

Where an owner employing a contractor to erect a building permitted the contractor to perform extra work under the theory that he should receive a specified sum therefor, and there was no fraud by the contractor in estimating the cost of the extra work, the Michigan Supreme Court holds that the contractor was entitled to recover the specified sum minus deductions for defective work.

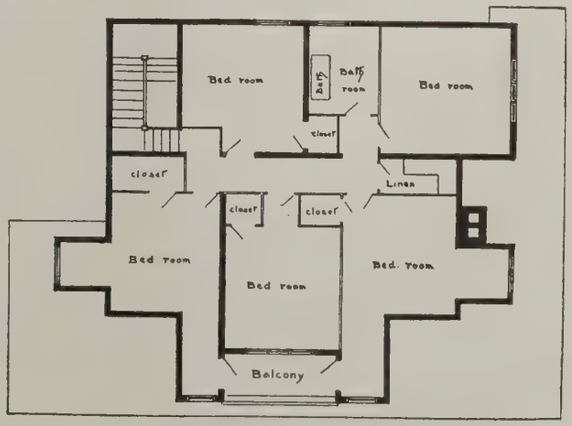
Plaintiffs furnished lumber and hardware to one who has contracted to build a dam, the materials being used in the construction of a temporary cofferdam. On abandonment of the work by the contractor, the owner took possession of the work, using for it the material which the contractor had left, including that in the cofferdam. The piling material constituting nearly one-sixth of the lumber, was substantially destroyed by use in the cofferdam, and a major portion of the planking when removed was capable of use in some other similar dam, and had at time of removal a market value of from $4 to $5 per thousand, but after removing it the owner used it in tramways and planking, and at the completion of such use it had no value except for firewood. At the completion of the work there would remain about 50 per cent of the lumber furnished, a large share of which would be unfit for anything but fuel, and the balance fit for use only in other dams and worth about $5 per thousand. The planking cost $16 per thousand and constituted about three-fourths of the lumber claimed. The hardware used in the cofferdam was of no value except as scrap iron.

The Supreme Court of Wisconsin held that there was such a consumption of materials in the erection of the cofferdam as to entitle the materialman to a lien on the permanent dam, under the provisions of the Wisconsin statute, giving a lien to the materialman who furnishes any materials for, or in, or about the erection or construction of any structure. The case also holds that where a materialman, as a convenience to the contractor, advances the freight on the materials, it was proper to allow such amount, on the theory that it was in substance a part of the purchase price, though it was not agreed in advance that such charges should be any part of the price.

AN ATTRACTIVE BUNGALOW

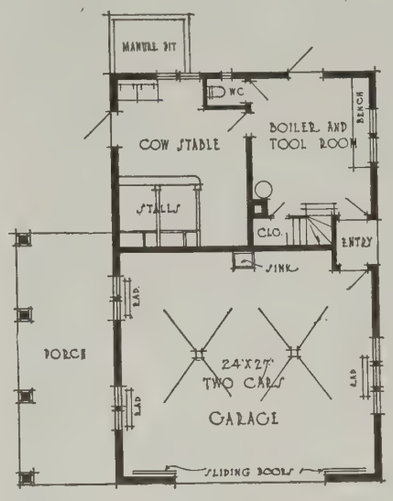


THE accompanying photograph of an attractive little bungalow designed by Mr. J. W. H. Watts, R. C. A., of Ottawa, Ont., and built by Mr. Robert McGiffin, Aylmer, Quebec, is a style of house that presents several features attractive to prospective builders. The exterior is constructed with the ordinary balloon frame and clap-boarded. The wide sweep of veranda is particularly attractive in a summer home, while the closed-in balcony affords a delightful and shady retreat. The interior is done in clear pine and spruce, natural finish, and varnished.

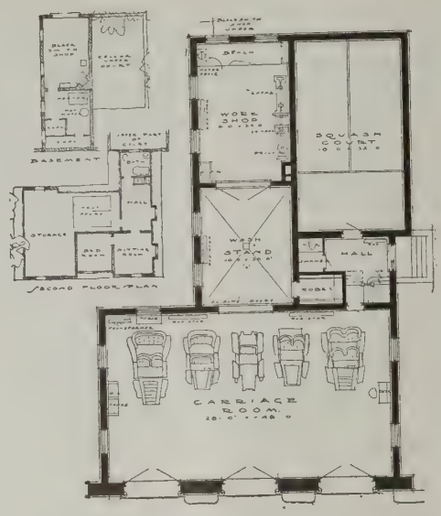


The sitting room is commodious and provided with an open fireplace and window seats. On the ground floor are also the dining room, with serving pantry adjoining, and a roomy closet. From the hall, which opens off the sitting room, a platform stair leads to the first floor, where there are five bedrooms and bath. To supply this latter, and also the kitchen, water is pumped from the lake to a tank.

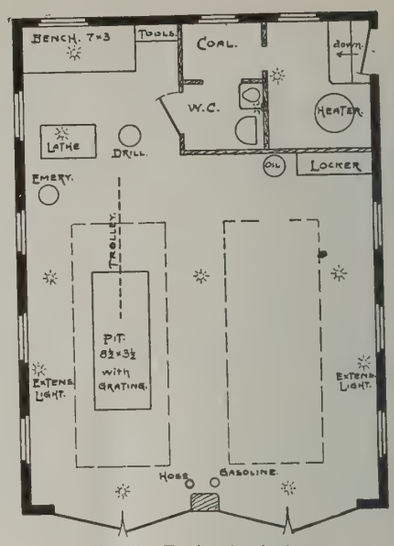
The kitchen is one story only and opens from the main hall. Access can also be had to the kitchen from the end of the veranda. To the rear are also woodshed and ice-house.



This bungalow would cost in the neighborhood of $5,000 to build.



PLANNING A PRIVATE GARAGE*



By HERBERT L. TOWLE

By Bailey & Bassett, Philadelphia.

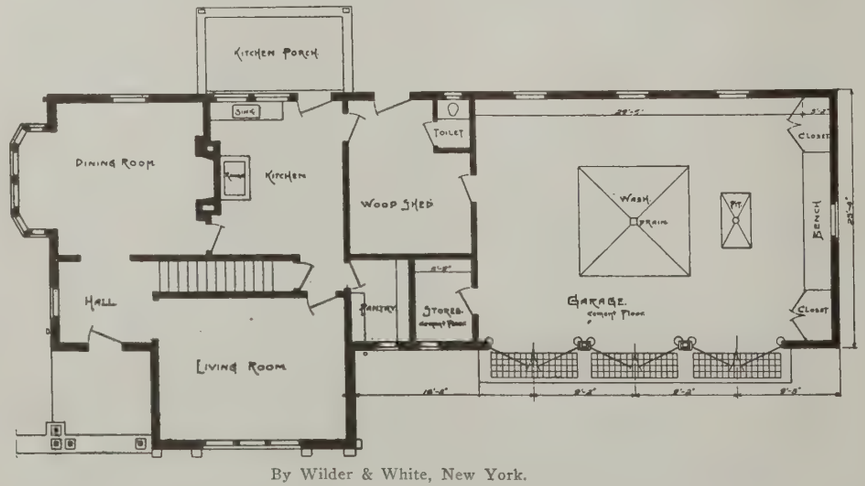
By Andrews, Jaques & Kantoul, Boston.

By Mr. Towle, the Author.

When a garage contains more than two cars a question arises as to the entrance and inside arrangements. Where the winter climate is not severe, undoubtedly the simplest plan is that of an individual pair of doors for each car. In freezing weather, however, a garage so arranged is hard to keep warm, unless the doors open on the south side. The next choice is a single door with a turn-table inside for backing each car into its proper place, which in this case should be crosswise of the entrance, as in a public garage. Failing a turn-table, skids may be used. If the garage houses but two cars it is simplest to give an individual door to each car.

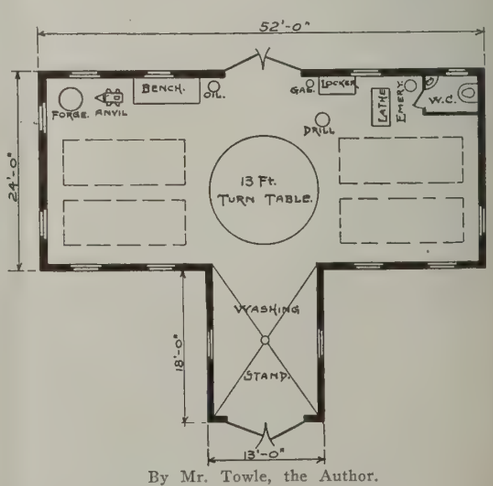
The usefulness of the turn-table has already been indicated. It occupies considerable room, since its diameter must be that of the diagonal wheel base plus an allowance of 6 inches or so for flattening of the tires, and this room cannot be used for any other purpose beyond washing the cars, for which purpose the turn-table pit is, of course, drained. For the one and two-car garage the turn-table is, therefore, a luxury, but with three or more cars it begins to justify itself.

A working pit is a luxury in much the same manner. It is a convenience where much repair work is to be done, and therefore justifies itself where several cars are kept in order.



For one and two cars the trundle already mentioned answers sufficiently well. The working pit, like the turn-table, must be drained, and it is advisable not to connect it with the general garage drain, in order to avoid the possibility of an explosion of gasoline vapor in the latter communicating to the pit.

When planning a garage for three or more cars, it is essential to arrange so that the movement of any one car shall not involve disturbing the other cars. The writer has seen garage floor plans otherwise excellent, in which this requirement had been wholly overlooked, with the result that a car coming in from the washing stand might find its way blocked by one or two other cars thus necessitating shifting the latter, and possibly running them outside to do so. In the plans is shown a floor plan with separate washing stand and separate entrance and exit in which the difficulty just mentioned is avoided by use of a turn-table. Any car can be run onto the turn-table, swung around, and run out front foremost, without disturbing any other car. The arrangement shown is limited to four cars. To accommodate a larger number, it would be best to build the garage like a round-house, with a storage room forming a portion of the circle, with a turn-table at the center. The washing stand could then be combined with the turntable, or better, perhaps, could be located separately, as in Figure 3, and the machine shop and paint shop could be located one on either side of the washing stand. Another arrangement would be to extend the plan of Figure 3 by adding another turntable and two additional cars on each side, flanking the central passageway over the turntable. Of course, by using skids the cost of the turn-tables may be saved, but to handle a car easily on skids requires three men.



It has already been mentioned that the hot water system of heating is the best adapted to garages. This is partly for the economy of the system, and partly because the garage will not suddenly freeze up, as it might owing to lack of steam if the steam system were used. The hot water is carried through pipes around at least two, and preferably three, sides of the garage. The pipes should be placed as low as possible, and in order to insure circulation, the heater will generally have to be depressed 2 or 3 feet below the floor of the garage, assuming that there is no basement. These small heaters are very economical, and three hods of coal will last a week in average New York winter weather.

Thus far architectural details of construction have not been mentioned. The available materials are stone, solid concrete, hol-

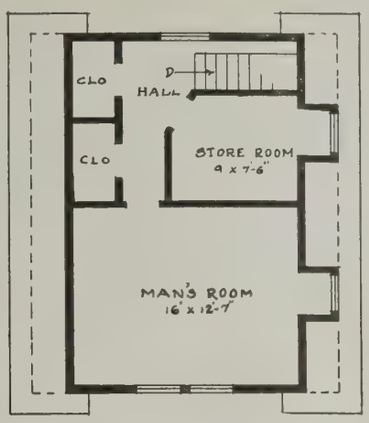
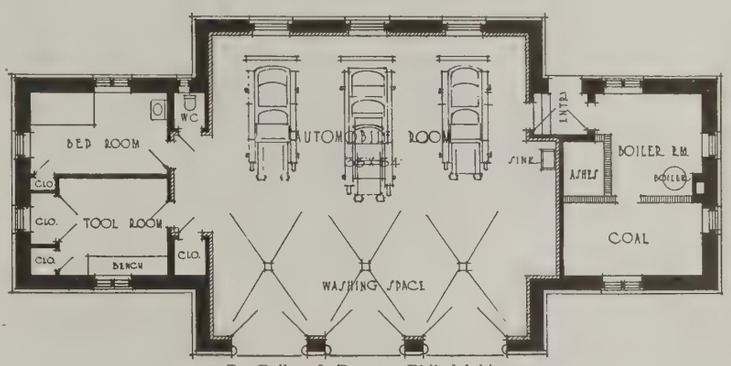
By Wilder & White, New York.



By Mr. Towle, the Author.

By Paul R. Allen, New York.

By C. E. Schermerhorn, Philadelphia.

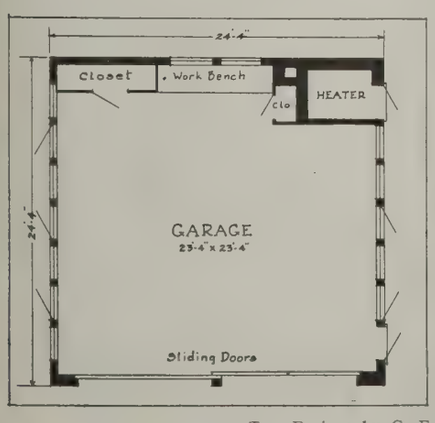


low tile, bricks, concrete blocks, stucco, wood and steel, besides, of course, portable houses of wood or wood and canvas.

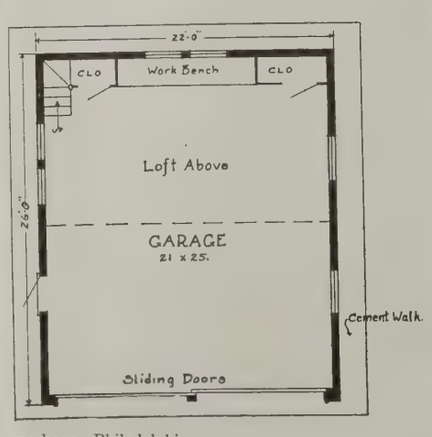
A highly desirable feature, and one difficult to attain in a small garage, is ability to resist sudden changes in temperature. A small garage, if not carefully planned, may become a furnace or an icebox in a few hours, and neither extreme is good for the car. High temperatures hurt the tires and the paint, and low temperatures sometimes lead to cracked water jackets and leaking radiators. From this point of view perhaps the best material of all is hollow tile, on account of the air spaces contained. Next to this comes a double wall of solid concrete, with an air space between the inner and outer walls. Stone is nearly as good, and may be quite as good if furred and plastered over laths inside. Bricks and concrete blocks are fair. Stucco, either wood or metal, though not absolutely fireproof, is a close approach to it if lathed and plastered inside, and resists temperature changes fairly well. Frame construction the writer condemns as not being fireproof. A portable house, by the way, becomes a permanent house in the eyes of the law, if planted on a permanent foundation of stone, brick, or the like. The proper thing is to place it on wood piling, which can be taken up.

The smaller the garage, the more necessary it is to have approximately weather-proof swinging doors. The writer has devised the arrangement shown in the accompanying sketch, for excluding rain and snow. A strip of canvas nailed to the bottom of the door would approximately serve the purpose instead of the swinging metal or board flap shown in the sketch. Owing to shrinking and swelling of the doors, absolute tightness is not to be expected, but by using weather strips of various sorts it can be approximated.

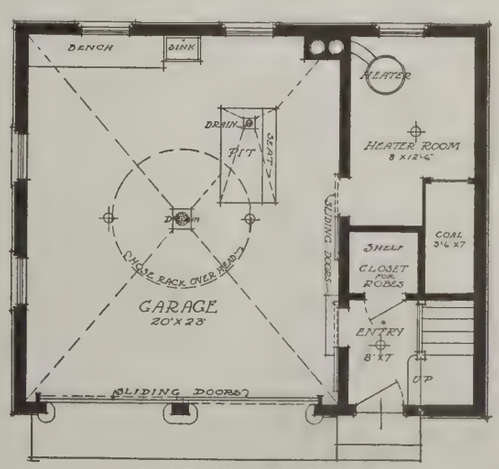
Whatever the construction otherwise, the floor should be concrete. It may drain to the center, under each car, or better perhaps, it may drain to a trench molded in the concrete and running all around next to the walls. The chief objection to the center drain is the possibility of a gasoline explosion in the drain setting fire to the car. The slope should be arranged so as to lead away from the floor about the bench and tools. For instance, in the sketches accompanying this article the drain trench may follow the dotted line of the curtain. It has sometimes been suggested that the water from the washing be drained out through the main doors. This is excellent except in winter, when the doors are liable to freeze fast. The better plan is to crown the floor as suggested, drain to right and left, and have the ends of the drains lead into drain openings just inside the door.



The lighting arrangements should give ample illumination both overhead and beneath, without direct sun if the latter can be avoided. Ribbed glass panes are excellent to intercept sunlight. The windows should extend fairly low, i. e., not more than two feet above the floor. If the expense is not too much, a northern



By Bailey & Bassett, Philadelphia.



skylight is admirable. The electric drop lights should be placed as shown in the sketch plans, one on each side near the motor, another over the bench, another over the lathe, if any, and at least one at the back of the car over the door. Extension sockets for side lights should be provided, at least one for each car.

Since many stables are being remodeled for garages, the foregoing suggestions may readily be extended to these also. A cement floor is desirable in all cases, to minimize the danger of fire. It can be laid on the existing floor by reinforcing the floor beams, if necessary. Additional windows should be cut in as needed, and the interior should be lathed and plastered. If the heater is located in the basement, it should be reached by outside stairs so that there shall be no possibility of heavy gasoline vapor settling into the basement and causing explosions.

Two Designs by C. E. Schermerhorn, Philadelphia.

By Paul R. Allen, New York.

POWER MACHINES FOR THE WORKSHOP

By GEORGE E. WALSH (Continued from June.)

II.

WITH the power question settled the carpenter anxious to fit out his shop with adequate machinery must select his woodworking tools and machines with a view to the class of work he intends to take up. The average shop is a growth, and not a sudden, fully conceived and planned thing. Success brings a greater pressure of work, and then the question of handling this economically comes up for solution. At first one may aspire only to a small band saw or table saw, but as the work increases he wants a turning lathe and a planer.

The tendency is toward the combination of machines in a single equipment, and through adjusting parts it is possible thereby to do a greater variety of work. For instance, a power saw outfit may be designed to accommodate a small and big rip-saw, a cross-cut saw, jointer-header, dado-header, and emery wheel. Thus in a single machine we obtain sufficient variety to meet almost all demands for a small shop. A single engine drives such a machine, and the carpenter finds much of his work simplified and greatly improved. There is far less handwork, and much less running to the mill to order every little piece of work.

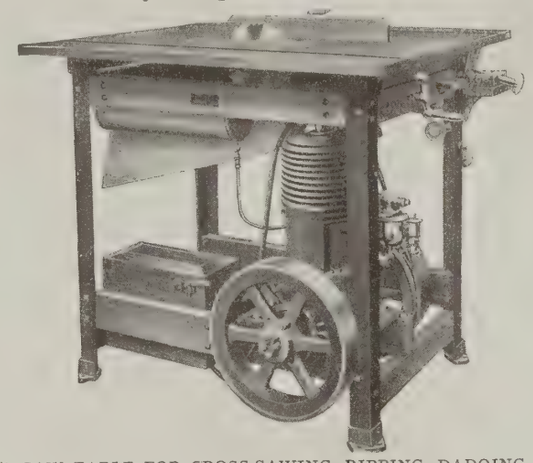


FIG. 1—A SAW TABLE FOR CROSS-SAWING, RIPPING, DADOING, BORING, ETC.

Simple and efficient table saws equipped for power connection can be purchased all the way from $50 up, and they can be used in a great variety of work. A rip-saw costs very little, and with one suitable for all ordinary work carpentry jobs can be done in much less than the usual time. Nearly every carpenter collects a considerable amount of second-hand lumber, and much of this could be cut up and utilized for odd jobs if a good power saw outfit was in the shop. Within a year's time one should save enough in this way to pay for the initial cost of the whole equipment.

Some carpenters stop at the rip and table-saw outfit. They never see the need of providing themselves with any further machines, but if the shop is equipped with power it is pretty certain that one will soon buy other tools to be run by it. Here naturally a good deal depends upon the character of the work the carpenter is doing. If he has jobs which call for a good deal of extra mill work he will in time add to his single machine.

Suppose, for instance, he has a gasoline engine of four or five horsepower coupled up to a table-saw. He has a surplus of power, and it would cost him practically nothing to operate one or two more machines. So he purchases a turning lathe and connects it by belt to the shaft. The turning lathe can be used for a great variety of odd jobs. It is almost as important as the rip and cross-cut saws. Odd pieces of lumber can be used, and instead of ordering odd pieces from the mill he can turn them out himself in the shop. It is sometimes pretty costly work to order from a mill a piece that will match something broken on a house, but it would be a simple matter to turn it out in the shop provided with a power lathe.

In the ordinary course of events the next machine that the carpenter would long for would be a planer molder or a jointer. This would prove a good investment if the class of work demanded it. With a molder of moderate size it would be possible to do odd door and sash work, and this pays in towns where mill facilities are not of the best. Of course, a complete equipment would call for a mortising machine. A good many have small foot-power mortisers already in their shops, but with gas power provided it would pay to get a heavier and bigger one. Then a class of work could be done that the ordinary carpenter with his foot mortiser could not do. A tenoning machine would add to the variety of work, and also a shaper.

By the time that these machines were installed the shop would be more of a woodworking plant than a simple carpenter shop. It would be equipped with machines costing several hundreds of dollars, and the owner would have to begin figuring interest on his investment to make good profits. It would be more in the nature of a small mill than a carpenter shop; but the line of work would be of a character to make this pay. No carpenter would purchase such equipments unless his work warranted it. There would have to be a demand for the machines before any one would purchase them. In other words the shop would be a growth, an evolution due to trade.

There is a need for such complete woodworking shops in every town. They are the connecting link between the small shop and the mill. Their operation would in time develop trade among other carpenters. Instead of going to a mill to have an odd job done, the average contractor would fall into the habit of sending the work to the carpenter shop equipped with the tools that could do it quickly and satisfactorily. With the tools and machines provided, the carpenter would naturally drift into cabinet work, and this is one of the best paying specialties of the trade. Cabinet work today depends as much upon machines and tools as upon

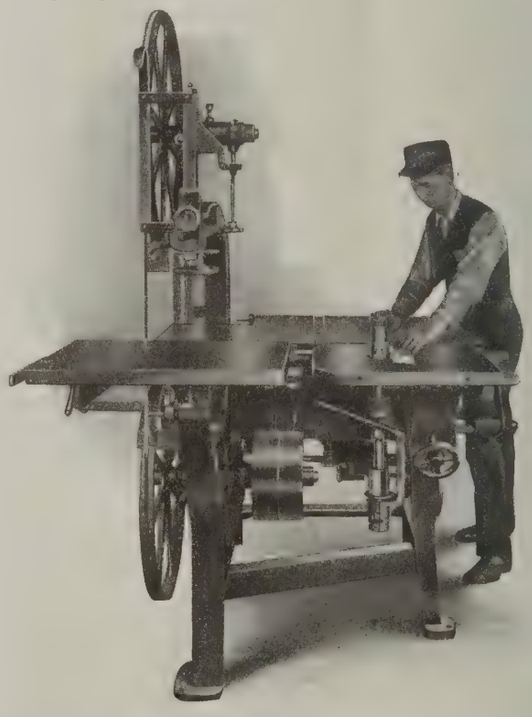

FIG. 2—COMBINATION MACHINE. PRACTICALLY A COMPLETE WOODWORKING PLANT. AS MANY AS 16 MACHINES CAN BE THUS COMBINED IN ONE.

any skill of the hand and eye. Three-fourths of the work can be done by machinery much cheaper and more satisfactorily than by hand.

There are plenty of instances of carpenters succeeding in this way and building up a flourishing business. As they saved money they purchased machines and added them to their shops. The character of work they could do advertised them and brought orders. The shop took on the character of a mill to some extent, and in time sufficient orders were obtained to pay for the employment of many helpers. One drifts into cabinet work, and another sticks to jobs and contracts of ordinary character. In either case the expansion of the business brought more work and greater possibilities.

The ambitious carpenter of today has more possibilities than ever before. He can reach out and bid for work that was never within his reach in the days when power machines were not adapted to the small shop. His shop may easily develop into broad lines and eventually become a woodworking mill on a small scale.

THE FOOLISH CONTRACTOR

By H.

There are so many contractors who are dilatory in finishing their jobs, with the result that they have much money due them and many dissatisfied owners, who are sure to do all they can to prevent other work coming their way.

We know of a Chicago contractor who seems to have no trouble getting work started. He is enthusiastic and gives the owners every reason to believe he is reliable. Being a ready talker he encourages the owner in every way; even does unusual things to gain his confidence, but before he is through with the job he lays down and then the owner's troubles begin. This contractor is known to draw ahead on his jobs, so well has he worked on the owner's generosity, and then he turns around and takes advantage of him. Why he does this no one seems to understand. There are many contractors who though they probably do not carry it quite to this extent, still they are apt to let small things remain undone. Whether they are paid in full or not, it is certainly to their interest to finish up their work and then forget about it.

As we look around, we find that the good contractor gets the best work. True it is that price counts with most owners. It is also true that the good man more often has the refusal of the job at even a better price.

The careless contractor does get some work, but to do so, it must be at a low figure. It's this low price he is obliged to make that keeps him from advancing and he is as a result always poor.

TO CARRY OR NOT TO CARRY A STOCK

To what extent should a carpenter contractor carry on hand a stock of materials? Of course, the very first thing to think about is the money end, but in this article we must assume that he has the ready money to carry a good size stock. Then, should he do so? There are, of course, many things to consider:

First: Is all of this work in his home town?

Second: Are his buildings of a like character?

Third: Has he a place to store the material?

Fourth: Does it pay on the investment, considering the advantages, allowing for damage and depreciation?

1. Of course, if he is an itinerant contractor he cannot afford to carry a stock on hand and ship or haul to distant points. The freight or drayage, adding thereto damage, would eat up any possible advantage he would have in buying cheaper in larger lots.

2. Unless his buildings are of such a class as to take the same kind of materials, he could not save money in keeping a stock on hand. If one job is a residence, the next a church, followed by a public building, the chances are the class of materials used would not conform to any of the stock he had on hand. The idea of having a stock is to use it up, and this means quickly. If he were to put in a stock of timber on which he saved $3.00 per thousand in buying carload lots, he could not afford to carry it on hand for a few years, but if he were putting up residences taking the lumber he bought, it would certainly pay him to lay in a stock. Such things as nails, screws, building paper and outside mouldings are used almost daily, and if there is a saving in quantity purchased, it should be done.

We are not considering here any possible advantage in buying away from home. Even your local dealer will gladly sell quantity lots cheaper than small lots. It costs money for a dealer to weigh out 20 pounds of nails, assorted kinds, and wrap them up separately. He expects to be paid for his time. If you bought a full keg, the whole time taken in handling this one full keg would be less than the wrapping up of a five pound order.

3. It would not pay to build a large place to store stock. It would take many dollars saved to pay for the cost of erecting a building specially for stock.

4. It only pays to carry a stock where the saving is considerable. Of course, its foolish for a contractor to go to a lumber yard and pay a cent a foot for fifteen feet of quarter round, when he could buy a few hundred feet at even less than thirty cents a hundred lineal feet. It's an item he always uses. This he should stock. There is a little loss from damage and depreciation, but consider the difference in cost—and so it is with nails and with building papers. These are staple with him. Every new job or repair job is apt to take some of it. The investment need not be large, not much room is needed to store it, and it pays to have it on hand for every emergency.

In the April issue of THE NATIONAL BUILDER we gave some short method rules of calculation. These cannot but benefit the young men if they will but take some little time in their study.

The aliquot parts of the table which was given in former article leads the way to practically all short rules of multiplication, division and substraction.

There is a short rule, however, which has no bearing on the table referred to, yet is so simple a process of multiplication that you are apt to wonder why you did not learn it at school.

THIS RULE IS APPLICABLE ONLY WHERE THE TWO UNITS NUMBERS ADD TEN AND THE TWO TENS UNITED ARE LIKE NUMBERS.

They are such multiplications as,

25	32	43	54	61
25	38	47	56	69

In the first one, the two fives add ten, while the tens numbers are alike (or like numbers.) This is true on all the above. In the second, the two and the eight add ten, and the tens are like numbers.

Here is the rule:

Let's take the first one.

Multiply 5×5 which equals 25. Set this down. Then say 2×3 (increasing the upper figure one number) equals 6. Set this down before the 25 and you have the answer, 625.

Now take the next one:

$8 \times 2 = 16$

$3 \times 4 = 12$

The answer is 1216

Prove it the long way of multiplication and see if it is not correct. You will wonder if this rule finds much application. It will work out even in fractions.

You have bought from your hardware man a lot of nails in a keg. His price is 2½ cents a pound and there are 25 pounds in the lot. What's the price? Answer quick 62.5 or 62½ cents.

Simply say 2.5c per pound
25 pounds

62.5

You point off the decimal same as you were taught at school. In working out the fractions you reduce them to decimals.

ARCHITECTURAL USES OF MICA

OWING to the great non-conductivity of ground mica, this mineral is coming into general use for insulating purposes. It has been found to be highly efficient as an insulator in walls to retain heat, on the one hand, or to prevent the entrance of heat on the other, as in the case of refrigeration. Ground mica as used for these purposes is not expensive and is one of the most satisfactory agents that can be employed. Walls lined with ground mica are about as well insulated as it is possible to make them. A similar use for mica is in deadening floors and walls. A layer of ground mica between floors will be found to be a very effective sound deadener.

The increasing use of cement blocks and cement construction of all kinds has made a new use for mica. Many architects are now specifying that the cement blocks they use shall be faced with ground mica. While the block is still plastic mica is sprinkled over its face to give it the sparkle and life of granite or marble, both of which contain a similar substance that adds greatly to the appearance of the work. In this connection it is worth noting that all the new cement monolithic lamp posts made for Lincoln Park, Chicago, as also the settees, drinking fountains and curbs of the same are impregnated with mica.

The fireproof qualities of mica make it an excellent finish for a ready roofing. It is a non-conductor of electricity and has many other qualities that recommend it to roofing manufacturers and users. For this reason mica-coated roofings are coming into very general use and are sustaining and extending their already good reputation.—American Roofer.

STAIRS AND THEIR CONSTRUCTION

(Continued from June.)

PITCH OF STAIRS.

It is found in practice that the best pitch for stairs is that inclination which by twicing the rise and adding the going equals 23. This agrees very well with the French theory: the labor of moving vertically is about twice that of moving horizontally, if the average human stride be taken as 23 inches.

Rise.	Tread.
5½	12
6	11
6½	10
7	9
7½	8

The limits of the variations of steps vary from 9x7 to 11x6 for ordinary purposes, and are the most useful in practice, the former measurement for ordinary and the latter for more important buildings.

WIDTH OF STAIRS.

The minimum width of stairs should admit of two persons conveniently passing each other. This cannot conveniently be done under 2 feet 9 inches, but 3 feet is the more common dimension of all ordinary work of a good character.

The winders should have at least the width of the fliers on a curved line 15 inches from the center of the newel.

HEIGHT OF STRAIGHT FLIGHTS.

To prevent giddiness the number of steps will vary with the pitch of the stair, 8 feet being the maximum vertical rise without a landing or turn. Greater heights should only be reached by flat pitches, such as 11x6 inches or 12x5½ inches.

WOOD FOR STAIRS.

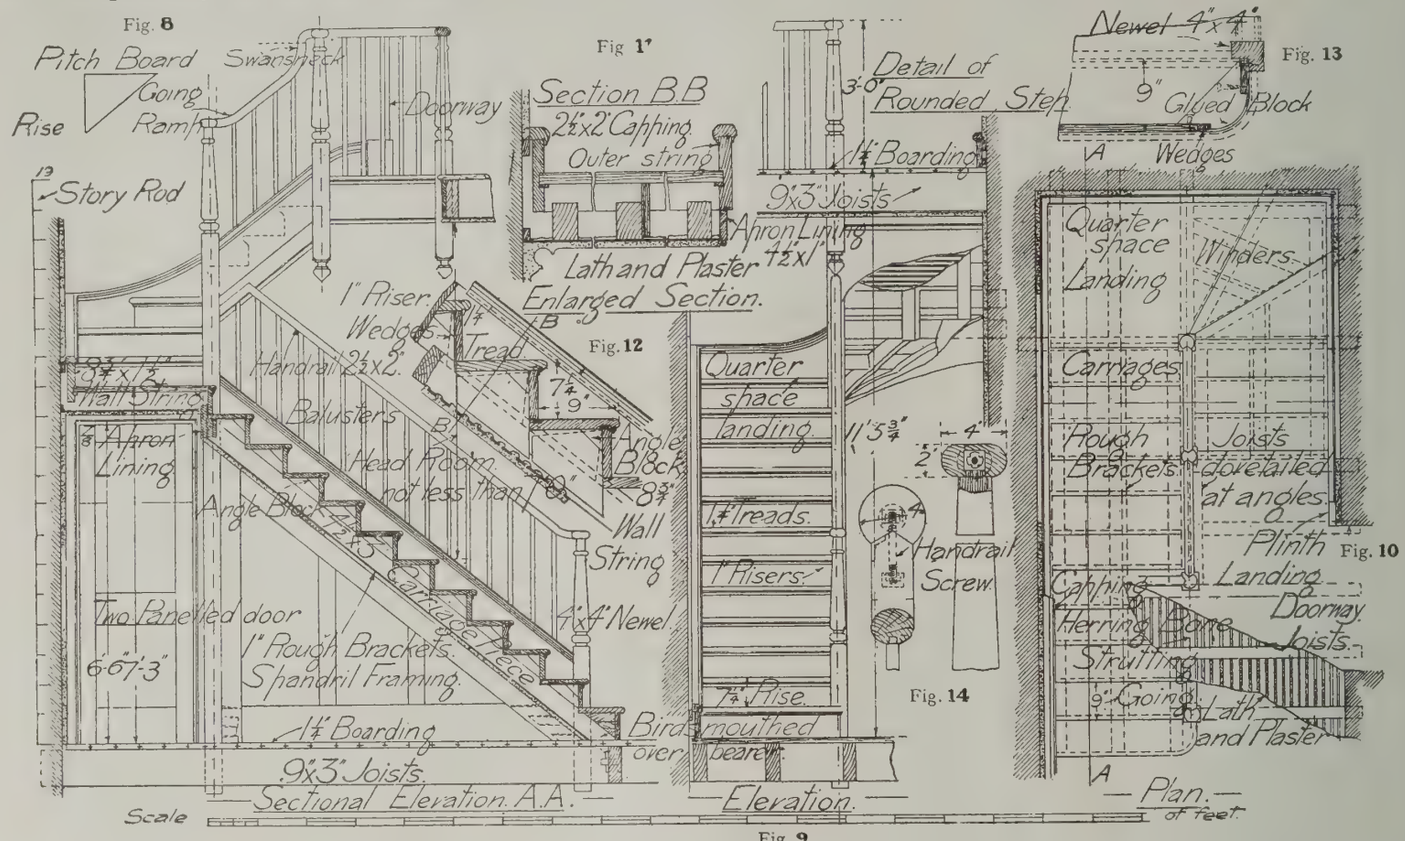
In ordinary practice pine is used for all parts of stairs, but oak and teak are used for more important work, and are better for resisting great wear.

Pitch-pine is hardly suitable, although often used for ornamental effect for all parts of stairs, but unless thoroughly seasoned it shrinks and the joints open.

Italian walnut, for its color and figure, is sometimes utilized for strings, balusters, newels and handrails of stairs. Mahogany and teak are preferable for handrails, as they are durable, ornamental and take a good polish.

FRAMING AND SETTING UP OF STAIRS.

The pitch and going are first determined, and a pitch-board made as shown in Fig. 5. The strings and newels are then dressed



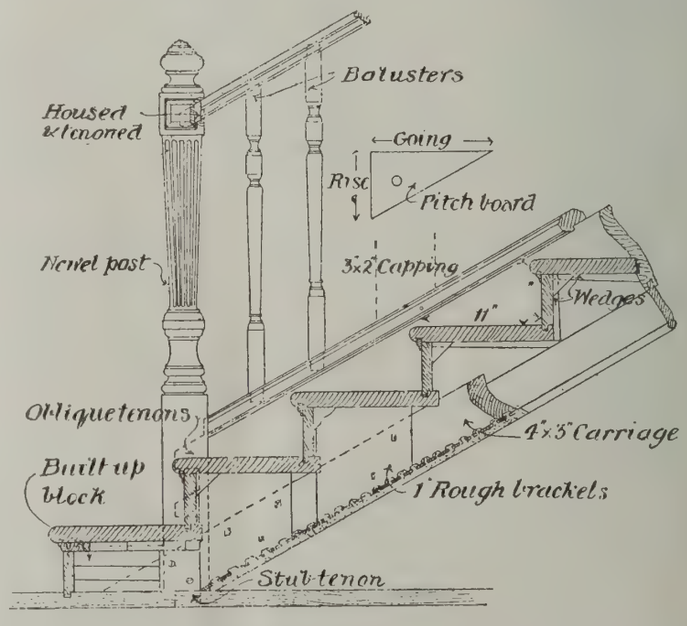


Fig. 9

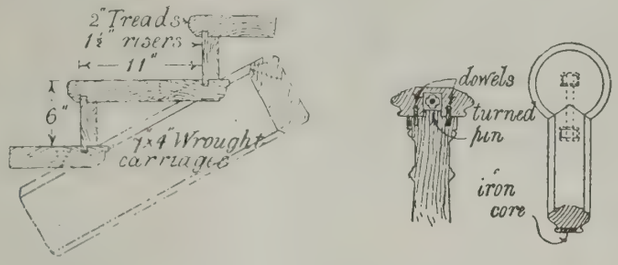

and set out by the aid of the pitch-board and plan of stairs; these are then housed, and the strings tenoned to the newels.

The risers and treads are prepared and fitted and glued; blocked to each other they form steps, and when set are fitted into the strings. After all have been fitted together the oblique tenons

of the strings are glued and doweled to the short newel, as shown in Fig. 5 (the longer newels not being secured until the work is in position, owing to the difficulty of transport); the steps are wedged to the strings, which then are ready to be fixed, and when *in situ* the rough carriages are then fixed beneath, and to prevent

distortion of the steps when subjected to rough usage, pieces of wood, termed brackets, usually 1 inch in thickness, are cut and fitted to the under side of the step and spiked to the rough carriages, and cut flush with the under side of the latter.

CLASSIFICATION.

Stairs are of two kinds: (*a*) Newel, (*b*) Well.

Under (*a*) come the straight, dog-legged, solid newel, and circular or rectangular.

Under (*b*) are included the open newel and the geometrical.

Straight stairs are useful for long narrow chambers; dog-legged for staircases the width of which is slightly more than that of two stairs; geometrical or open newel for those chambers of a greater width.

Open newel stairs present the best appearance and are strong.

Geometrical stairs require care and a good deal of skill in their construction; they are not so imposing as the open newel, and are comparatively weak; they were extensively used in middle-class houses of the Georgian period.

NEWEL STAIRS.

Figs. 8 to 14 show plan, section, elevation and details of steps adaptable to newel stairs, showing treads, risers, rough brackets, rough carriages, wall and outer strings, cappings, apron lining, and plaster soffit.

Fig. 13 shows the form of construction and method of fixing a quarter-round bull-nosed step by a block glued and screwed and formed of three pieces, the grain of each pieces crossing the other at an inclination, forming the fixing for the sunk and wedged riser.

Figs. 7 to 14 give the working drawings showing pitch-board, story-rod, handrail with ramp and swansneck, and showing accurately all the necessary details.

LAYING AND SCRAPING OF OAK FLOORS

Oak flooring requires some care in laying, as it is very easy to ruin, by incompetent workmanship, what would otherwise be a perfect floor. Judgment must be used in selecting the different pieces so that they shall blend well and the floor shall present an even shade, and not be dark and light in streaks. This can be done if a little care is used.

If the floor is to be laid over an old floor, remove the quarter-round and sweep the floor clean. Lay the new strips at right angles to those of the old floor. In new houses, the sub-floor is usually laid diagonally. The top flooring is laid across the joists, starting from the longest straight wall, and striking a chalk line from end to end just far enough from the base-board to admit one piece of flooring. Nail the first piece of flooring straight on this line, setting the nails well through the piece. Then start by selecting the light-colored strips and laying aside the darker ones until all of the light pieces have been laid. Then select the lightest of the dark, and so on, until the floor is finished. By doing this, a floor of even color can be obtained. This is the most important part of laying oak floors. When the hearth is reached, miter a hearth-strip or a piece of floring around same, continuing until the wall is reached, and then nailing the last piece through the face in the same manner as the first piece was nailed.

If more than one room is to be laid, it is much better to select separate shades for the different rooms, laying the light stock in the darkest room. It is best, when laying over old floors or sub-floors, to use a good quality of damp-proof paper or deadening felt under the top flooring.

The flooring should be securely nailed. On 3/8 and 1/2 inch, the nails should not be over six inches apart; on 5/8 and 13/16 inch, not over eight to twelve inches apart when laid on sub-floors, and twelve to sixteen inches when laid on joist. On sub-floors, the nails should be "staggered." Be careful in nailing not to mar the surface of the floor in driving up the nails.

While there are a great many machines made for scraping floors which give good satisfaction, on high-class work it is much better to do this by hand, using a cabinet scraper. This part of the work should be done with the greatest care, as proper scraping is essential for a perfect finish. Always scrape lengthwise of the wood—not across the grain. No amount of sand papering will remedy the defects in scraping, such as wavy surfaces or the strokes left by the knife. These defects show much more when the floor is finished than when it is being scraped. A floor properly scraped looks very smooth, but still it should be thoroughly gone over with "No. 1½" sandpaper to obtain the best result in finishing. This should be done carefully by getting on the knees, throwing the weight of the body on the sandpaper, and running it in long, even strokes with the grain of the wood. When the work is done, the floor swept clean, and the dust removed with a soft cloth, the floor is ready for the finish.

HYDRATED LIME FOR WATERPROOFING CEMENT MORTARS

SINCE void filling is to be sought as the panacea of waterproofing ordinary field concrete, comparative tests through the additions of percentages of colloidal clay or hydrated lime and the various advertised waterproofing compounds have been carried on continuously with the conclusion at this date that no general results are obtainable from the additions of patented or proprietary compounds which cannot be obtained equally well through the use of colloidal clay or hydrated lime.

Additionally, it seems to be very generally proved by corroborative tests, results of which will be submitted later when long-time results will be available, that, as stated in last year's report, to be likely a weakening in tensile strength in time followed the use of many of the patented compounds, which effect is not generally marked when colloidal clay or hydrated lime is used. It has been concluded that the so-called patented compounds fail to remedy defectively proportioned concrete of poor materials as effectively and positively as colloidal clay or hydrated lime simply because they do not carry sufficient fine material called for by existing conditions. The apparently waterproofing effect of some of these proprietary compounds at early stages, with the very common loss of strength later on, only confirms the opinion as to their temporary effect being mechanical entirely, in aiding, through deposits, to fill voids to the desired end, which can be permanently better assured by the use of proper percentages of fine material such as colloidal clay or hydrated lime.—American Society for Testing Materials.

MECHANICAL HOISTS

ONE of the articles of progress of the mechanical equipment that comes in to relieve the burden of hard physical labor in building is the mechanical hoist, a power hoisting apparatus for conveying building material from the ground to the upper stories of the building.

These have already received a fair amount of attention from the builders of large buildings, those which run more than two stories high, but many a carpenter and contractor specializing in residences might also help himself and add to his profits by taking up with something of this kind.

The trouble with the average man doing comparatively small construction work is that he looks upon all of these things as being within reach only of those big contractors who handle the large undertakings. This is an idea that should be gotten rid of, because in this work, as in woodworking machinery, there has been a lot of special attention given lately to devising equipment expressly for the lighter work, portable equipment that can be easily moved from one place to another and even still lighter equipment that is operated by hand.

The gasoline engine and the electric motor have made practical many things in light power driven hoists and the ingenuity of mechanics has also made possible several improvements in hand power hoists that will do much to lessen the burden and insure the safety of handling material from the ground up on to the building and a really progressive builder cannot afford to let these things pass by without investigating.

A BUILDER'S COURSE IN ARCHITECTURAL DRAWING.

RALPH F. WINDOES.

(Continued from June.)

PLATE XIV.

WITH this plate we begin the actual study of architectural drawing. The previous plates were of an elementary character and were introduced to familiarize the student with the use of the drawing instruments and also to acquaint him with the fundamental principles of drawing.

As was stated in a previous lesson, the plan of a building is a representation of each floor as if the building were cut between this floor and the one above it, so as to show all doors, windows, stairs, etc., in their proper relation to each other and to the rooms

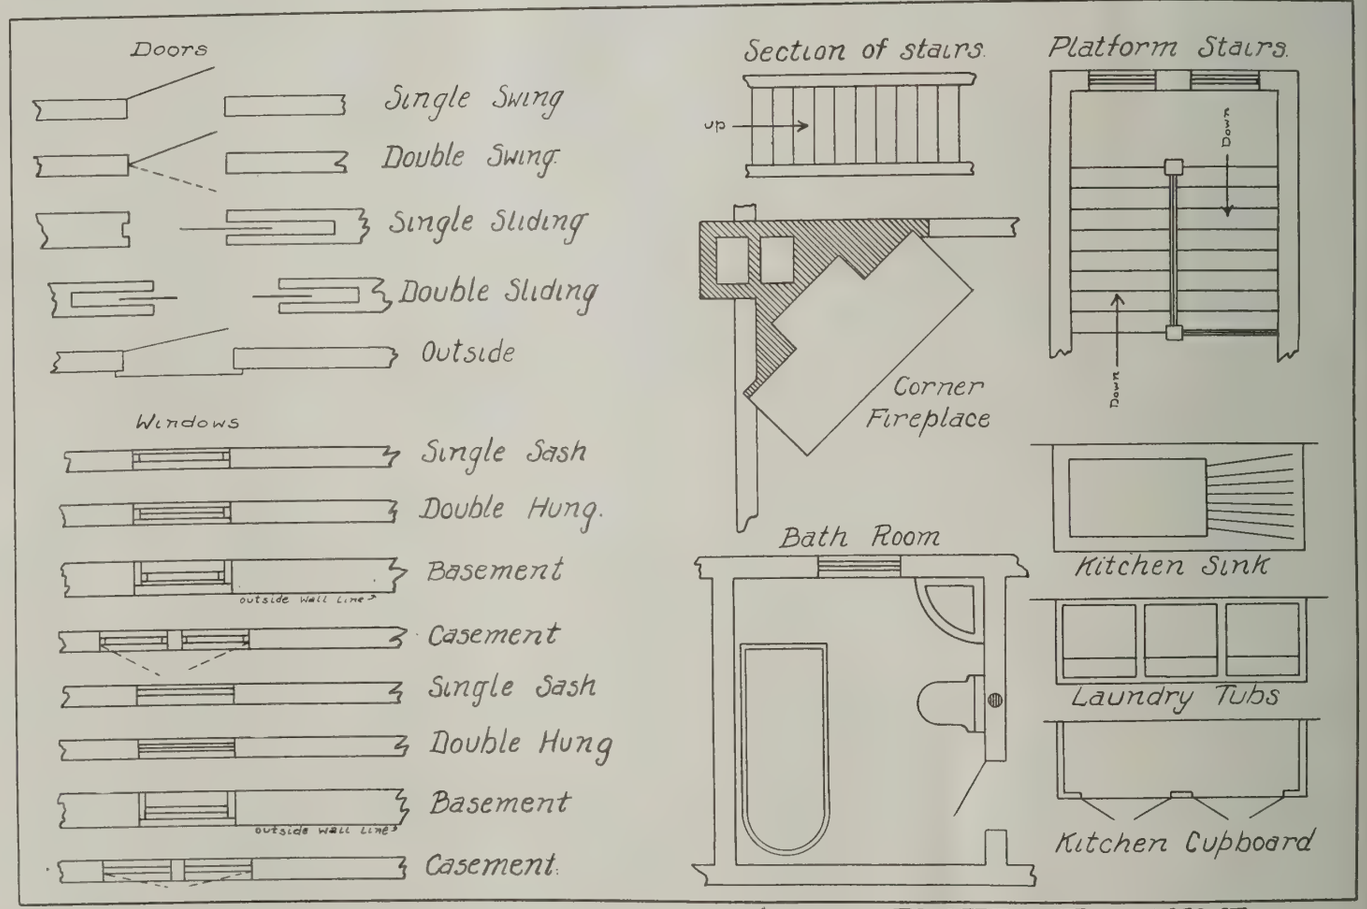

PLATE XIV NAME.

of the floor. It is evident that it would be almost impossible for the draftsman to show the plan as it would appear if so cut as each individual stud would have to appear in section, each window and door frame as if they were cut in two, and all of the other parts, as lath, plaster, siding, etc. So draftsmen have established a conventional method of representing these parts on their plans and when an actual section is to be given they draw it in detail to a larger scale.

Of course the elevations appear as the sides of the completed building would appear.

Now let us consider Plate XIV. The student should make a careful study of this plate and the one following it and should be perfectly sure that he understands every figure perfectly. The conventions here given are largely for a frame building.

The first elements shown are the doors. The first one of these is the single swing door. It will be noticed that the walls are represented each side of the opening as two parallel lines. Th door itself is a single line swinging from one corner of the oper ing in the direction it is to swing in the completed building. Th second one is the double swing door. This is drawn in the cente of the opening, a solid line in one direction and a dotted line i the other. The third is a single sliding door and the fourth a dou ble sliding door. It will be noticed that the walls here are thicke The last door given is an outside door in which the threshold represented.

Next on the plate are shown the windows. The first thin apparent on these is the fact that the windows are not shown openings in the wall, but the wall line runs past them. On th first four the outside and the inside sills are both shown as a also the sash openings and the glass openings. The last four a modifications of the first in which the glass openings are left o It is easy to understand that they should be there and the leavi of them out saves the draftsman much time. Notice the diff ence between the single sash and the double hung windows. A the basement window in which the frame is shown. The ca ment window shows which way the sections swing, also the m lion in the center for each sash to strike upon.

Remember that these representations are only conventio with a certain number of draftsmen and some others may have different system of which there are a great many, each of which h its own particular merits.

Next the section of a stairway is given. It will be understo that in a plan only the treads can be shown, that is, the horizon

members of the stairs. The vertical portions, or risers, can only be shown in detail or in a vertical section. Notice the arrow and the word "up" which are always given on plans. The riser is generally figured at 7 or 7½ inches. The tread then must not exceed 10 inches, as the sum of the two must be 17 or 17½ inches. This shows us that the narrower the tread the higher the riser and vice versa. In planning stairways we must always know the ceiling height of each floor in order to determine how many risers we need, and from this how many treads to put in. In the next figure we have a platform stair as drawn in a second floor plan. Notice the walls and the two windows, also the newell posts and the handrails, etc. Starting from the top we go down nine steps to the landing, then down until the steps disappear under the floor. They are completed on the first floor plan.

A convenient method of representing an inside corner fireplace is next shown. The section lines show the brick as distinguished from the wooden partitions. The flues, one for the fireplace and one for the kitchen range and furnace, are each 8 by 12 inches inside. The hearth extends out into the room about 18 inches. An inside well fireplace is shown in the same manner, but of course it has a rectangular shape.

The bath room conventions are given comprising a tub, a seat and a corner basin. A vent is shown in the wall directly back of the seat.

The kitchen sink is shown with a drip board. Laundry tubs should be represented as illustrated. The kitchen cupboard should have doors swinging out unless there is room for sliding doors.

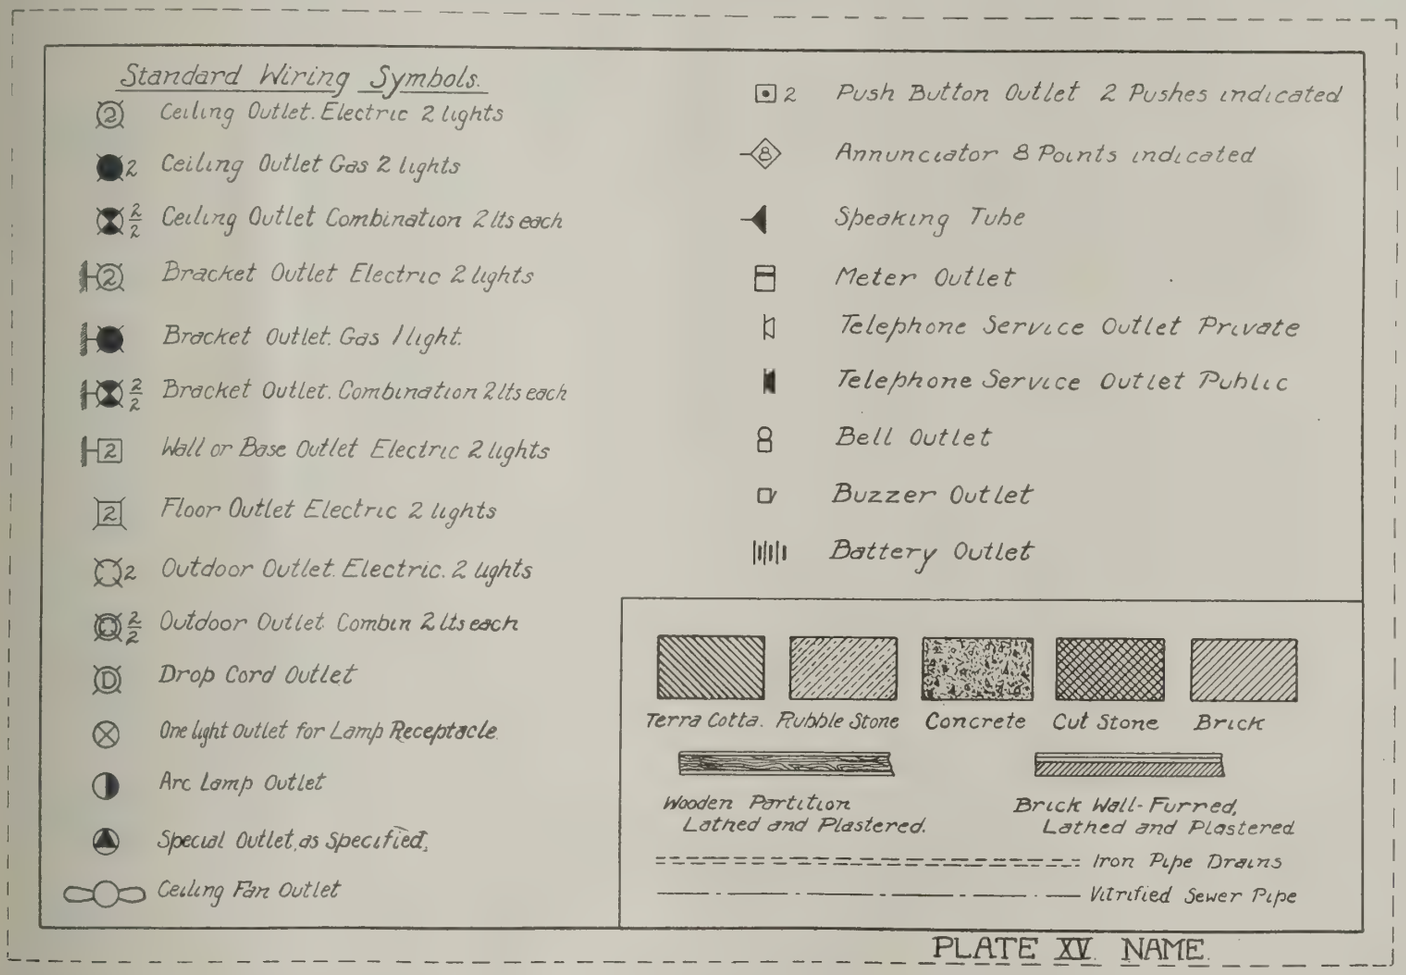
The student should make his drawing at a quarter-inch scale, remembering that the walls on a frame building are 6 inches thick.

PLATE XV.

This plate is largely taken up with Standard Wiring Symbols as represented on plans. The symbols here illustrated are those adopted by the National Electrical Contractors' Association and the American Institute of Architects. Complete copies may be obtained from the secretary of the Association at Utica, N. Y., or from the secretary of the Institute at Washington, D. C. It is advisable that every student obtain a copy.

The symbols are self-explanatory and it is a very easy matter for the student to draw them in, properly lettered.

In the lower right-hand corner of the plate a few conventions are given. Here we have the representations of some building materials when they are shown in section. Notice that terra cotta is the same as brick with the lines running in the opposite direction.



A wooden partition in a frame building may be shown in detail as illustrated. Plaster is represented by parallel lines on opposite sides of the wall.

The brick wall shown is furred on the inside and plastered.

On basement plans various lines of pipe are sometimes shown. For the sewer connections inside the building and extending 6 feet outside the wall, the iron pipe drain should be used. Then it should be connected with the vitrified pipe and carried to the mains. Both pipe representations are here illustrated.

There are a large number of conventions used that are not on either Plates XIV or XV. These will become familiar to the student as the work proceeds, or when he goes into an office as a draftsman.

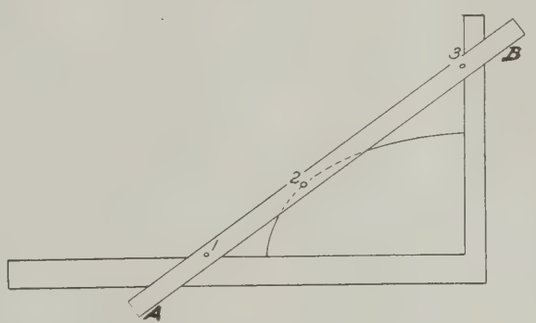
(To be continued.)

Mr Alfred Hudson, before the Royal Institute of British Architects, said:

"One of the first matters with which an architect will have to deal when he confers with his employer is the question of cost, and to this all his ideas must be made subservient. For this purpose he must be trained to measure and estimate, and he must learn the value of different materials. It falls to the lot of very few architects to find clients of unlimited means, and it is still more rare to find even such clients willing to disregard questions of cost. Another example of equally necessary instruction is the proper specifying of the materials, and the various works which are required to be carried out. This is a matter in which great foresight is required, besides a knowledge of every kind of detail. One of the first essentials in the student's instruction should be to teach him to describe accurately the various materials and methods of construction upon which he is receiving instruction during the course of his studies. It is not uncommon to find that a specification has been copied from an obsolete model inscribing materials which have ceased to be sold, or even manufactured."

OUR READERS' PAGES

[The Editor does not hold himself responsible for the opinion of correspondents. Short, crisp letters will be appreciated. To insure publication, the name and address of the writer must accompany the communication, not necessarily for publication. Sketches of work or methods will receive our earnest attention. These columns are open to our readers at all times without charge, and any questions or experiences will be given proper space.—Editor.]



ANSWERS

TO DRAW AN ELLIPSE WITH A SQUARE.

Answer to J. E. L., Shenandoah, Iowa.

In a thin strip A-B locate the points 1, 2, 3. Two being a hole for a pencil. One and 3 being brads projecting slightly below the strip. The distance 1-2 is equal to ½ the minor axis; 2-3 equal to ½ the major axis.

Place the square with the inner angle at the center of the ellipse. Slide the strip, keeping the points 1 and 3 against the square, as shown, and the point 2 will describe one-quarter of the ellipse.

FRAMING.

From a "Wood Butcher."

In reply to H. C., Mansfield, Mass., and Young Farmer, Seattle, will say, brothers, that a good square and roof framing is my hobby. I have an old Eagle square with the old board scale on that a carpenter never uses. I also have had a square for twelve years, and would advise all brothers to use one like it in a locality where framing is done. It has a rafter rule on it, giving figures for lengths per foot run of rafters, and side cuts, for more pitches than H. C. will ever frame in his lifetime. Get No. 100 ox. copper as advertised on page 20 of May NATIONAL BUILDER. Now if you want side cut for hip rafter, say for 10-inch pitch, look under 10 on the blade-line 6, gives you 13-15. Cut on the larger number always.

Now, brothers, buy two books also; "The Steel Square and Its Uses," by Fred T. Hodgson. This will give you more tricks with the steel square and roof framing than you will ever have occasion to use. On page 85, volume 11, we find length of rafter, rim and side cut, which to my satisfaction is absolutely correct. That means, H. C., if your hip rafter is 18 ft. long and the run from the corner of plate to a point plumb under the top of the hip rafter is 15 ft., 18-15 on your square gives you the side cut to fit common rafter, ridge board or deck—anything that is at right angles to your plate line, length and run of your common rafter, cut jacks, etc. If you get figures too large to work on square, diminish equally by dividing both figures by the same number. Thus, 18-15 would be 9-7½ or 6-5. Don't forget to use a little mental effort with your work, and learn to be a keen mechanic.

SOLDERING COPPER.

From A. M. C., Chicago.

Replying to H. Schroll, St. Louis, Mo., with regard to soldering copper, the process is identically the same as soldering tin, except that cut acid is used for the flux in place of rosin. The acid is cut by dropping pieces of zinc in muriatic acid until it will not dissolve any more. For the best work, it is necessary to tin the joints first, which is done by applying a little of the acid and covering the edge with solder by running a hot iron over it. This leaves a thin film of solder on the edge where the two pieces are jointed together. This can be a half inch or more wide, according to the lock of the joint. It is necessary to have the iron rather hotter than for soldering tin in order that the solder may be sweated well into the joint.

GYMNASIUMS.

From E. N. B., Maywood, Ill.

Reply to J. W. A., Birmingham, Ala.

In regard to gymnasiums, the best articles on the subject which the writer has seen published came out in The Bricklayer, published by Rogers & Manson, Boston, Mass., in the February, March, April, May and June, 1909, issues. You can probably obtain these at the publishers, or possibly they are in the files of your public library. Some thirty or forty gymnasiums are shown in plan and elevation with considerable instructive reading matter.

FROM N. E. N., KALAMAZOO, MICH.

In regard to the question on hip rafters in the May issue, the correspondent no doubt made the mistake of using the figures for common rafters in obtaining the side cut of hip, in which case it would not make a joint.

The rule for finding the side cut of any rafter is to take the length and the run of that rafter on the square, cut on the length. So to get the side cut of a hip rafter, take the length and the run of the hip rafter, cut on the length—not the length and run of the common rafter.

JACK RAFTERS.

From K., Vancouver.

In reply to "Slivers," Flushing, N. Y., who wants to know how to get the side cuts for jack rafters, also hip and valley rafters, I will say that if he will get one of Nicholl's framing squares, he will have just what he wants. With it he can get the lengths of any rafter either common, hip, valley or jack with bottom and top cuts, also side cuts of hips, valleys and jacks for any pitch roof he wants. If he gets the 1¾ tongue, he will find it handy in laying out studding, etc. He should be sure to get the pamphlet that comes with the square.

SIX, EIGHT, TEN.

From R. R. D., Fillmore, N. Y.

Squaring a foundation of a building with a ten-foot pole, 6, 8 and 10 is done like this: Commence on corner of building, measure off six feet on one side and eight feet on the other side. When the building is square the ten-foot pole will reach across exactly to these two marks.

From "Old Framer," La Crosse, Wis.

"Country Contractor," when squaring a foundation by this method should measure off, on one side of the line, eight feet exactly, and this line should be a front or main face of the building, and must not be disturbed when once determined. Then stretch another line at right angles to the first, and on this measure off exactly six feet, with your ten-foot pole; and if this distance between the six and eight foot marks is just ten feet, your lines are at right angles, or square, with each other. If not, move the second line at its loose end until the points make the necessary distance. I will not give you the reason why the 6, 8 and 10 rule is correct, as that is uncalled for at present, though pleasingly instructive to those who do not know it.

DAMP-PROOF WALLS.

From "Builder," Port Huron, Mich.

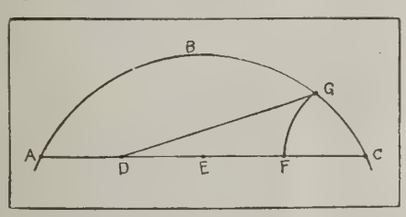
I am afraid "Plasterer" of South Bend is up against a pretty difficult proposition, as the trouble evidently is caused by the damp creeping up from the foundation wall, and this can only be cured by proper draining of some sort, and the drain tile should be placed below the level of the foundation footings and have an outlet, either is the town's draining system below the walls, or into a cesspool lower than the level of the walls. Cementing the

walls will not serve your purpose, but will break away from the brick wall and eventually flake off. You could, of course, dig below the footings and take out the lower courses of brick or stone above the footings, and insert some damp-proof courses, such as slate, or asphalt, underpinning and securing the work as you proceeded, and then if the earth outside was above the dampproofing it could be removed and plastered with cement mortar to a little above the earth line. This would make a good job of it, but would necessarily be a little costly. The cement mortar for such work should be formed of two parts sharp sand and one part cement. Rake out all the loose mortar from joints in brickwork and brush clean with a stiff brush, then flush the whole wall with water, and lay on the mortar while the wall is damp. Float and trowel well, and do not let dry too rapidly.

HOSPITAL.

From "Architect," Montreal, Canada.

If "Committeeman" of Edmonton, Northwest, will enter more into details, and describe the requirements needed, his question could be, in a measure, intelligently answered. There are hospitals and hospitals, and designers of new ones require special training in order to be able to turn out the best building for a given sum; and it follows that very little real useful information can be given in the short reply I must make here. However, it may be well to point out some of the conditions necessary, that are often overlooked in designing the small hospital.



The heating should be of the low pressure hot water system of ample capacity. There should be a well ordered method of ventilation, and there should be, in the larger town hospitals, provision for sheltering families who have been temporarily dishoused while disinfecting operations are being carried out in the houses. There should be a proper mortuary provided, one side of which should abut a passage through which the interior of the mortuary may be inspected, through a heavy plate glass window. Isolation rooms in proper location must be prepared under correct conditions, and supplied with all modern improvements. I would like to extend these remarks, but want of more particulars and lack of space at my disposal forbid. Give us some more particulars.

(Note: If "Committeeman" will send his correct address to this office, we will put him in communication with "Architect" and several other specialists, if he desires.—Ed.)

MEASURING A CIRCULAR ARC.

From "Bolivar," Cornwall, N. Y.

Perhaps the following is what "Young Bricklayer" wants: To find the length of the arc ABC, first draw the line AC and

divide into four equalt parts by points D, E and F; then with C as a center and a radius CF, draw arce FG. The line DG is then one-half the length of the required arc.

SIDING FOR CIRCULAR TOWER.

From E. N. B., Chicago, Ill.

In answer to D. S. P., Scranton, Pa.

To find the radius to work beveled siding to for a circular tower: Divide the radius of the tower in inches by the thickness of the thickest edge of the siding, and multiply by the width of the siding in inches. For a two-foot radius of tower, with three-inch siding one-half inch thick we have $24 \div \frac{1}{2} \times 3 = 144 = 12$ ft. The siding will have to be in short lengths to allow working it to this short radius, but by using clear wide siding, cutting out at top in the center and on the ends on the bottom, it can probably be sprung around all right.

Sometimes it is necessary to have special siding worked out in the mill with a ship lap joint at the bottom, thus letting the back lie flat against the sheathing or studs. In such a case be careful not to make the relate too deep at the bottom, or there will be a joint seen. It is better to leave it a little tight, as a plane will soon fix the top of the last piece put on.

QUESTIONS

RAISING A FRAME BUILDING.

From J. B., Golden, B. C.

What would be the best way to lift a frame building 75 ft. by 35 ft. to a height 10 ft.

SOUND PROOFING.

From H. M. H., Leadmine, Wis.

We have a hall used as an Odd Fellows Lodge room on second story, and as a store on the first. When it was built, to deaden the floor they laid deadening felt on the joist, then laid the floor on the felt. This plan was a failure as one can sit in the store and hear the talking that is going on above. What would you recommend to deaden the floor so that it would stop the above trouble. The size of the building is 20 ft. x 40 ft. with 2x12 joists 16 in. on centers.

STRENGTH OF WOOD BEAMS.

From E. C., Chicago, Ill.

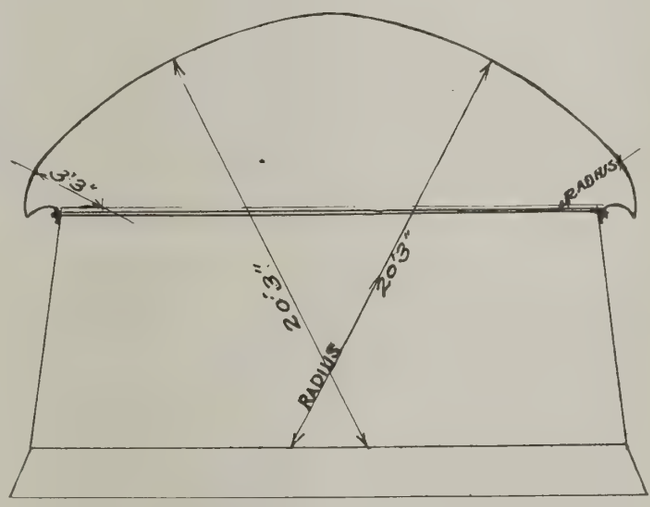
I would like to ask the editor or some reader who is competent, to publish any formulæ calculating the strength of wood beams.

OCTAGON ROOF.

From G. R. A., Bruce, Mich.

I wish to build a building with eight equal sides and would like the roof to be built Mansard style. What pitch would look best, and how do you get the cuts of rafters without drafting the whole thing?

SILO DOORS.



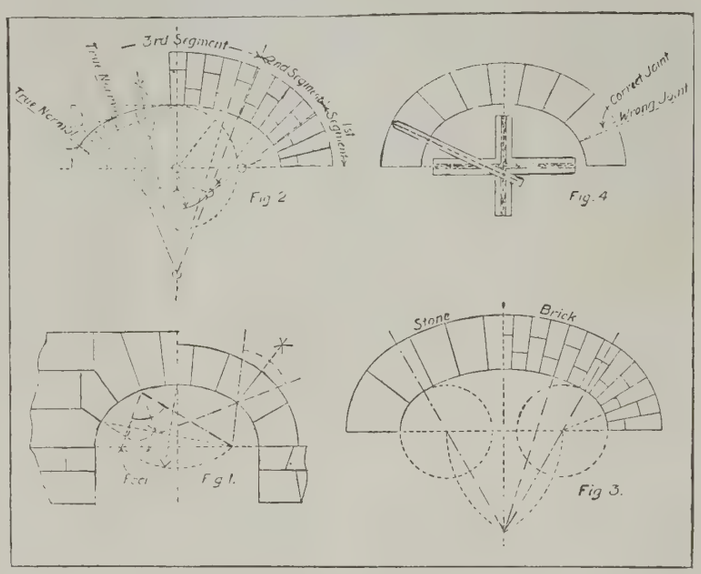
From R. R. D., Fillmore, N. Y.

Please give me the best idea of silo doors, commencing at top and going all the way down.

FRAMING CURVED ROOF.

From C. J. H., Ogden, Utah.

I should like to know the most accurate and easiest way to lay out the hip rafters for a roof as shown.



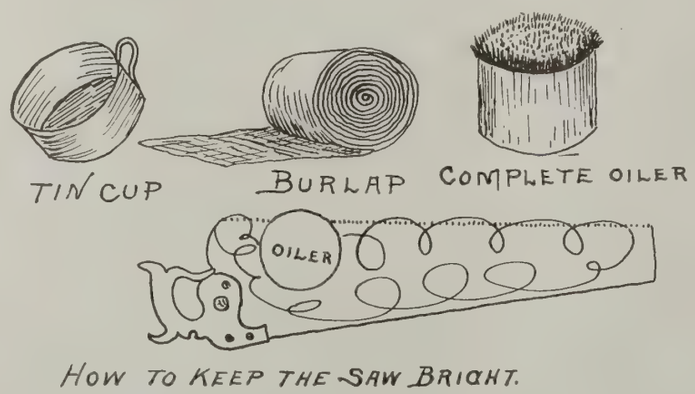
SELECTING HAND SAWS.

From a "Boy Apprentice," Kansas City, Mo.

In a few months I will have served what may be called an apprenticeship, but which is in reality the completion of a mutual contract, in which I agreed to work so many years at the carpenter and joiner trade for a fair consideration and a good chance to learn the trade. Just as soon as the time expires I intend to purchase a good working outfit of tools—the best in the market. I have already secured a few, and I would like, if such of your readers as may feel inclined, will advise me as to what kind and make of hand saws are the best, from their experience in the use of them. Just now this is a live matter with me, and I will feel obliged for any information or suggestion in the matter.

OUR PRACTICAL PAGES

THESE drawings show several methods of drawing joints for elliptical brick or stone arches. Fig. 1 shows the correct method of jointing and stepping for to receive ashler, Fig. 4 shows the trammel, as before mentioned, and the joints here have been purposely set out wrong in order to show the trap into which



so many fall when using the trammel—viz., setting out the joints to coincide with the centre line of trainer upon trammel. The correct joints are normal to the soffit curve (see Fig. 1) Fig. 2 is an approximation of the ellipse, and handy for brickwork. The junctions of segments are joints in a true ellipse. Fig. 3 is of the same span and rise, and is set out by what may appear to the novice as a simple method. With stone arches, divide the intrados for voussoirs. For brickwork divide the extrados, place a whole brick in centre for key (see Fig. 2) and divide round.

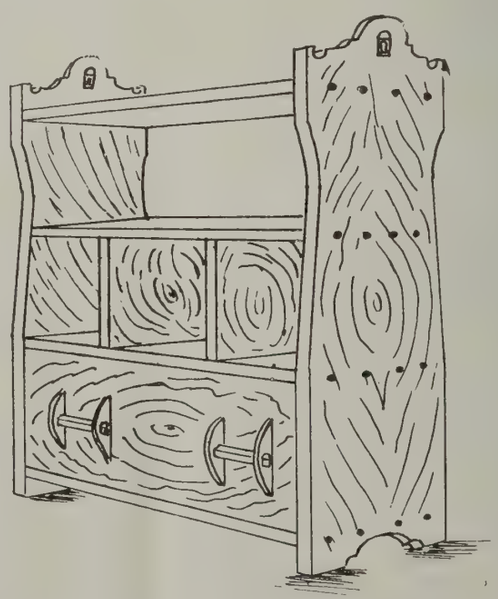
OILER FOR HAND SAW

By W. A. LANE

Keeping saws bright and free from spots is not an easy thing to do, while oiling them with a cloth is rather a mussy affair, so if this oiler is tried once I think all will like it. Take a small tin cup, or part of a tin can, about 2½ inches deep is a good size. Cut a strip of burlap, or some similar material, 3 inches wide or ½ inch wider than the depth of the receptacle used. Roll this tight, having the roll large enough to be a very sung fit into

the cup. The part which projects should be raveled out to form sort of a stubby brush. Soak this cloth thoroughly with oil and it is ready for use. Keep it well saturated all the time and when oiling the saw, use a circular movement as shown in the drawing. Should there be any spots or rust on the saw, sprinkle a little emery dust on the oiler. Before sawing lumber containing much pitch, rub the teeth of the saw with the oiler and they will not become gummed.

THE sideboard shown herewith is designed in a simple and effective style, and may be easily made by any careful workman in wood. The original from which this photo is talken, are made of quartered oak and polished, but there is no reason why it may not be made of other woods. The three panels in the back



of sideboard are formed of bevel glass mirrors, and the upper panels may be formed of leaded colored glass, oil paintings, or framed chromos or prints, to accord with taste or extent of purse.

A MISSION BOOK CASE

By EDITH C. LANE

AS women use furniture more than do men, I think they have clearer ideas as to what is most useful. In this piece of furniture I have a combination affair, saving space in the room, and the expense of extra pieces. At the bottom is a large roomy drawer, this will hold drawing materials, stationery and many needful things, right at hand, yet are not exactly "things of beauty" when lying around a room. The next shelf is in three compartments and serves to hold different size books. The top shelf is large enough for several magazines and a pot of flowers or

A MISSION BOOK CASE.

a vase with one's favorite blossoms. At each end there hangs, in the opening, a small bell, as in the old mission towers. The lines are very simple, so that the man of the house can easily construct it, while the madame herself may enjoy staining it. It may be made of ordinary pine and stained to harmonize with the other furniture in the room.

METHOD OF OBTAINING HIP-RAFTER HEAD BEVELS

THIS article is written with a view of giving a method of obtaining the edge cut for the head of a hip-rafter in any case where the rafter fits against the side of the ridge.

First Example.—When the end and side-walls are at right angles and the plan of hip-rafter bisects the angle between walls (see Fig. 4), fix a line as shown in Fig. 1, and set a sliding bevel or a steel two-foot to the angle at A. Apply this to the side of the hip-rafter, and draw ab (see Fig. 2). Next set a pair of wing compasses to the thicknesses of the hip-rafter (in this case 2 in.), and with any point on ab as center describe an arc as shown. Tangent to this arc and parallel to ab draw cd. Draw from c square across upper edge of rafter to e. Join e to a. This gives the edge cut and ab is the side cut. If the upper edge of the hip-rafter has previously been "backed" or beveled, then the edge cut must be set out on the lower edge.

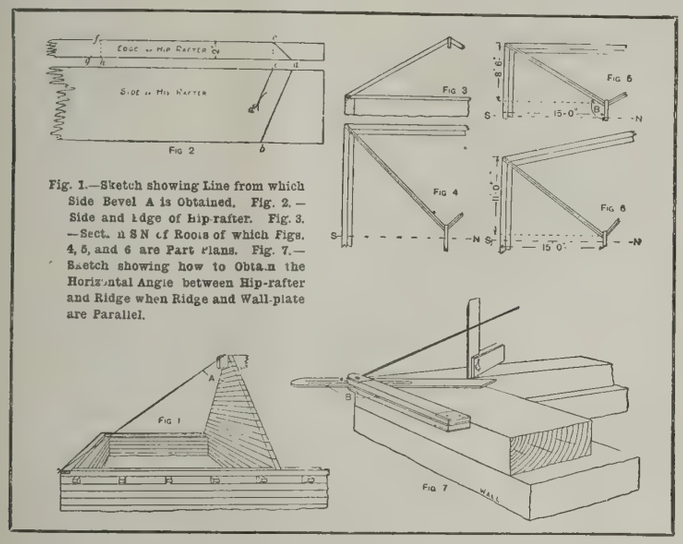


Fig. 1.—Sketch showing Line from which Side Bevel A is Obtained. Fig. 2.—Side and Edge of Hip-rafter. Fig. 3.—Sect. on S N of Roofs of which Figs. 4, 5, and 6 are Part Plans. Fig. 7.—Sketch showing how to Obtain the Horizontal Angle between Hip-rafter and Ridge when Ridge and Wall-plate are Parallel.

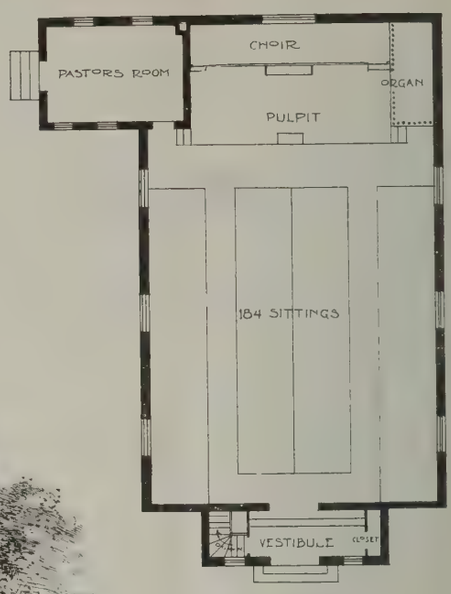
Second Example.—When the end and side walls are at right angles, but the plan of hip-rafter does not bisect the angle (see Fig. 5), proceed just as in first case, but instead of thickness of hip-rafter as a radius, use a measurement which may be obtained in two ways, both of which are given as follows: The first way is to set a sliding-bevel to the angle between ridge and hip-rafter on plan (see B, Fig. 5). If a plan is not available angle B may be obtained as shown in Fig. 7, providing that the ridge and wall-plate are parallel. Apply the sliding-bevel thus set anywhere on edge of hip-rafter and draw fg (see Fig. 2). From f draw square across edge to h. Then gh is the required radius. In the second way the radius is got by using the measurement, $8\frac{1}{2}$ ft. and 15 ft., given on Fig. 5, to make the fraction $\frac{8\frac{1}{2}}{15}$, and multiplying this by the thickness of the hip-rafter. Radius $= \frac{8\frac{1}{2}}{15} \times 2 = \frac{17 \times 2}{2 \times 15} = \frac{17}{15} = 1.13$ in., or $1\frac{1}{2}$ in. full.

Third Example.—When the end and side walls are not at right angles (see Fig. 6), proceed exactly as for Example 2. Here the required radius will be 1 7/16 in. full. Radius $= \frac{11 \times 2}{15} = \frac{22}{15} = 1.47$ in., or 1 7/16 in. full.—Building World.

The attention of people who are able to read is constantly being directed to the poor economy of investing in cheap things. This is particularly true with regard to that which is intended for the home. That which is inexpensive is not always to be scorned, but inexpensiveness is not necessarily cheapness. The policy of furnishing a home well, if slowly, is very much better and usually more profitable in the long run, than at once furnishing the house with cheap materials. That this applies even to little things is shown by the news of the serious condition of an entire family, caused by sleeping in recently papered rooms. Arsenic had been used in making cheap wall paper.—Furniture.

AMATEUR CARVING

THE illustration of the piece of carving shown herewith is the work of a boy—A. S. Burroughs of Melville, Sask. On inquiry we have discovered the boy has had no training only such as was given him in the manual training school of the little town in which he lives, and that his opportunities for obtaining knowledge of the art of carving have been limited and of short duration, and chiefly confied, he states, to the instructions given in Fred T. Hodgson's work on "Practical Wood Carving." His tools were few and consisted of a small set of amateur wood-carving tools. The material out of which the figures are graven is douglass fir—not a very good kind of wood for the purpose. The figure measures 21 inches high by 15 inches wide. This is a



remarkable piece of work to be wrought by a boy scarcely out of his teens, who has never seen any sculptural work of note and had no opportunities for the practice or study of the art, but who has been obliged to work during the day, since he was able, for his livelihood. The boy is more than clever, and his work gives indications of his possessing the qualities, in a large measure, that go to make an artistic carver.

This example shows what may be accomplished by earnest application and perseverence, and it speaks well for the habits of the boys who inhabit that far-off northwestern part of this continent, if they are formed on the same lines as this "Mellville Lad."

It is a portion of their duty to be among those who will help this cause of proper fireproof construction upward. They must recollect that not only are there thousands of dollars consumed each year from this single cause in this country, but they must bear in mind that precious lives are too frequently sacrificed in these catastrophies that could be saved, if there was more intelligence and care exercised by both manufacturers of materials, and constructors of buildings. When each man considers himself a committee of one to enforce this law of right and duty, then we may hope to see a full realization of the age for which we are all so eager, that of the epoch of fireless disasters.

Notice.—All books noticed in these columns may be obtained from this office at Publisher's prices. All postage or express prepaid. Money and address must accompany all orders.)

THE CONSTRUCTION OF CONCRETE FENCE POSTS, prepared by the office of Public Roads, United States Department of Agriculture, Washington, D. C. Farmers' Bulletin No. 403.

The growing use of concrete has been the subject of much investigation and experiment in both public and private laboratories. Not only is the monolithic skyscraper the subject of much thought, but even the farmer's fence posts are carefully considered. In the bulletin under discussion, the experiments of the government engineers show that the cost of concrete posts does not vary greatly from the cost of wood posts under ordinary conditions, while the concrete post lasts practically forever without repairs or replacement, and after three months' curing are as strong as wood at the strongest and increase in strength while wood retrogrades.

Various forms of posts are shown and the drawings will enable one to manufacture the posts, either at home for use on the place or in a yard for sale to farmers and others. The Bulletin is sent free by the Department of Agriculture.

PLUMBING AND HOUSEHOLD SANITATION, by J. Pickering Putnam, member of the Boston Society of Architects and of the American Institute of Architects. Many illustrations, 718 pages. Price in cloth, $3.75 net, postage 35c.

A course of lectures delivered before the Plumbing School of the North End Union, Boston.

In common with most other authorities who have given close study to the science of sanitation, the author believes that the present laws and systems for caring for sewage and plumbing waste are susceptible to material improvement. As our present systems, designed during the few years, are utilizing the same principles in vogue almost back to the Dark Ages, if not Roman times, it would seem just that such revision be made as will bring the sanitation on a level with the more recent discoveries, inventions and methods.

In the course of the discussion, the author asks for simplicity, reducing the amount of unnecessary machinery, piping and fitting now connected with the fixtures, accessibility, exposing practically all piping, as a workman is certain to be more careful when his work is forever open to inspection; avoidance of mechanical obstruction, trapping the fixtures by a water seal only, and cutting out balls, valves, gates and other unnecessary obstructions; tightness and flexibility of jointing, making all joints permanently tight, and avoiding the use of substances which are apt to be injured by use, changes of temperature, shrinkage, etc.; soundness of material; thorough ventilation from end to end of soil and drain pipe; adequate flushing; automatic and noiseless operation, and economy and prevention of water waste. While all these principles are admittedly good, there is difficulty in finding the most practical method of obtaining the results, and still maintain the high standard of efficiency required under modern conditions. Too often leniency on the part of the engineer or inspector results in faulty work, thus causing the very defects it was intended to avoid, so it cannot be left to the workman to decide how a system can be simplified. The work calls attention to many matters which should receive careful consideration from law-making bodies, as well as engineers, architects and workmen. The experiments of the author show why these reforms are needed.

The volume contains a review of Dr. Teale's interesting work on "Dangers to Health." Did we not know that even worse examples are found in the country, it would be hard to believe that such conditions as are here shown were found in England. On the whole, it is possible that conditions in the better districts of the large cities are better than on the average farm, and it may be that a little well directed effort toward the improvement of "Farm Sanitation," would be well rewarded by increased health on the farm and purity of milk and other farm products.

The volume is the result of twenty-five years' research and study of sanitary plumbing from both the theoretical and practical standpoints. The simple and popular style in which it is written renders it of value to the needs of the general public as well as to legislators and sanitary engineers.

THE ENGLISH STAIRCASE; an historical account of its characteristic types to the end of the eighteenth century. By Walter H. Godfrey, architect, author of "The Life and Works of George Devey" and "The Parish of Chelsea." Illustrated from photographs by Horace Dan, etc., and from measured drawings and sketches. Published in London by B. T. Ratsford, 94 High Holborn street, and imported by Charles Scribners' Sons. Price, $7.50 net.

Few parts of a building, public or private, are more in view than the staircase, and none have received more attention from the architects and builders of modern times. The development of what might be termed "domestic architecture," was truly centered about the main hall and its staircase, and it is with the historical development from the early fifteenth century to the late eighteenth that the author especially treats.

At the beginning of this period there were but two commonly used styles of stairs, one a straight flight of enclosed stone steps, the other a winding circular stair, also of stone with little or no attempt at elaboration or ornamentation. In France the development of the stairway led to the most elaborate stone vaulting or brick work, while the tendency in England soon manifested itself in the form of woodwork in an open well.

The author has made a great effort to properly classify the work and characteristics of the various periods and has collected an exceedingly interesting number of illustrations to accompany the historical sketch. The charm of simplicity is shown as well as the ornate and magnificent, and the plates, as well as the measured drawings, faithfully represent the sequence of architecture during the periods included.

ELECTROPLATING. A TREATISE FOR THE BEGINNER AND FOR THE MOST EXPERIENCED ELECTROPLATER. By Henry C. Reetz. Pouplar Mechanics series. Price, in cloth, 25c.

This book is one of the series of handbooks on industrial subjects being published by the Popular Mechanics Company, and like the others which have been reviewed here from time to time, is written so as to be understood, not by the scientist but by the one who may have occasion to refer to it. The information contained is apparently correct and complete, and is intended to give brief and practical directions to those already engaged, or about to engage, in the electroplating business. Unnecessary technical detail is omitted, and yet such explicit directions concerning the actual operation are given as an old hand at the business would think might be useful to the beginner.

Among the subjects treated are plating with copper, nickel, silver and gold, as well as the necessary shop equipment, and preparing the goods for plating. A chapter is devoted to the treatment of accidents due to the use of the materials employed, many of which are extremely poisonous and dangerous.

PROPERTIES AND USES OF DOUGLAS FIR, by McGarvey Cline, Director Forest Products Laboratory and J. B. Knapp, Assistant District Forester. Published by the United States Department of Agriculture.

The purpose of the bulletin is to present the facts about the properties and uses of Douglas fir, as collected by the Forest Service.

Tests were made at the laboratories of various universities and other reports were obtained from many manufacturers and users. The tests made were very exhaustive and should be of value in future working with this material.

There are approximately 350,000,000,000 feet broad measure of Douglas fir in the western states, which makes it the leading American wood. The list of uses to which Douglas fir is put includes mine timbers, railway ties, bridge timbers, car material, all kinds of lumber for houses, furniture, boats, as well as miscellaneous commodities.

OUR HOME CITY, by William Arthur, author of "The New Building Estimater," "The Contractors' and Builders' Handbooks," "How to Build American Homes," "Everybody's Building Book," etc. 133 pages. Paper covers. Price, 25c.

The dream of the idealist has often centered on the model city, sometimes with a view of residence, sometimes business, and too often without fixed ideas at all. Seldom have we seen cities rise by a predetermined plan, or even follow well-thought-out lines. For the conveniences of today we can easily plan, but as even now our streets and cities are not ideal for automobiles, and practically no provision made for airships, how can we tell what our wants will be a hundred or even fifty years hence?

In this volume the author endeavors to interest the reader in advanced lines of thought regarding ownership of land and public utilities, sanitation, amusements, etc. It is proposed to lay out, where the topography will allow it, a symmetrical city, complete with wide streets, parks, boulevards, etc. In other words, lay out for a present population of 5,000 the municipal system which will serve as a center for the needs of an unknown population years hence. As we have no means of knowing what the future will develop, there is no way of determining which way the trend of population will be, or why. Should the town grow one-sided, it would mean expensive improvements wasted on the prairie, and possibly a city with two business centers.

The book is well worth reading, as it shows up many of the inherent defects in our present cities and towns. Whether it is possible to forecast the future sufficiently to obtain the necessary land before the real estate boomer gets it, is another question. The plan suggested would, if it worked out, alleviate many of the present day troubles, but the writer is reminded of a certain city in Asia designed and planned with the greatest foresight, only to pass from Russia to Japanese control before it was finished.

PATENTS.

The following list of recent patents and trademarks relating to building interests is especially reported for THE NATIONAL BUILDER by Wm. G. Henderson, solicitor of American and foreign patents and trademarks, Norris building, 501 F street, Washington, D. C. A copy of any of the United States patents will be furnished by him for 25 cents.

994,091. Reinforcement for concrete construction. H. Brussel, assor. to Reinforced Concrete Co., St. Louis, Mo.

994,001. Sash-lock. Chas. Hunt, Newburgh, N. Y.

993,457. Metal-door construction. F. E. Nelson, Jamestown, N. Y.

993,930. Expanded-metal structure. H. E. White, assor. The General Fireproofing Co., Youngstown, O.

994,448. Track for door-hangers. H. L. Ferris, assor. Hunt, Helm, Ferris & Co., Harvard, Ill.

994,325. Truss-bar for concrete construction. D. Maxwell, Detroit, Mich.

994,336. Collapsible core for constructing hollow concrete walls. Wm. T. Redman, Brentwood, Md.

995,212. Door-closing device. Jno. P. Bair, Belvue, Kans.

995,008. Reinforced-concrete wall and like structure. Geo. W. Jackson, Chicago, Ill.

995,069. Reinforced concrete construction. H. L. Lewen, San Francisco, Cal.

994,961. Window-ventilator. J. Steinhelper, Williamsport, Pa.

995,665. Door-check. A. Danielson, Chicago, Ill.

995,673. Door track and hanger. Geo. J. Hatz, Omaha, Neb.

RECENT COURT DECISIONS

Where a subcontractor abandoned the work before it was completed, he could not maintain an action for the value of the materials furnished and the work done without justifying his default.—Berkstrom v. Ryan, 122 N. Y. S. 878.

Where the scaffold from which plaintiff fell was erected by inexperienced men, the boss directing the work, and with ordinary care he could have made the staging safe, the fellow servant doctrine does not arise.—Craesafulli v. Winston Bros. Co., 108 P. (Idaho) 740.

Where the scaffold from which plaintiff fell was erected by inexperienced men, the boss directing the work, and with ordinary care the boss could have made the staging safe, the question of assumption of risk does not arise.—Craesafulli v. Winston Bros. Co., 108 P. (Idaho) 740.

Where the scaffold from which plaintiff fell was erected by inexperienced men, the boss directing the work, and with ordinary care the boss could have made the staging safe, the question of contributory negligence does not arise.—Craesafulli v. Winston Bros. Co., 108 P. (Idaho) 740.

The surety of a firm of building contractors cannot escape liability on a bond for performance of a contract by the firm for the construction of a building for $37,994 on the ground that the owner should not have let the contract to a firm which had undertaken contracts to the amount of $200,000 on a capital of only $400.—Y. M. C. A. of North Yakima v. Gibson, 108 P. (Wash.) 766.

An excavation, made by an adjacent owner, so as to take away the lateral support, afforded to his neighbor's ground, by the earth so removed, and cause it, of its own weight, to fall, slide, or break away, makes the former liable for the injury, no matter how carefully he may have excavated. Such right of support is a property right and absolute.—Walker v. Strosnider, 67 S. E. (W. Va.) 1087.

Where competent men were employed to erect a scaffold for the use of themselves and co-employes, and suitable material was furnished therefor, and they were not instructed outside of a direction to construct it, and a co-employe not present when the scaffold was built thereafter fell and was injured on account of defective construction due to the use of improper material, the employer is not liable.—Muehlman v. Spokane & I. E. R. Co., 108 P. (Wash.) 764.

Where a subcontractor, having abandoned the work before completing his contract, filed a lien for the whole sum mentioned for the entire work, on the theory that the contract remained in force when the lien was filed, nearly a month after the work was abandoned, and that plaintiff was still continuing to perform it, such lien claim was inconsistent with the complaint, seeking to enforce the same for the reasonable value of plaintiff's work and materials on a quantum meruit.—Berkstrom v. Ryan, 122 N. Y. S. 878.

A building contract requiring the contractor to file receipts with the superintendent and owner showing that each subcontractor had been paid in full to the amount of the estimates, as per the certificate of the previous month, etc., does not require the superintendent or the owner to exact receipts for all claims for labor and material, a subcontractor being one who takes from the principal contractor a specific part of the work, and does not include laborers or material men.—Y. M. C. A. of North Yakima, 108 P. (Wash.) 766.

Where plaintiff owned a lot on which he intended to conduct a lumber business, and had contracted to pay for a stock of lumber, and paid the freight on the shipment, and had actually placed a small part of the lumber on his lot, his contract to sell the lumber purchased, and not to engage in the lumber business in the town for two years, was not a sale of merely a right to engage in the business, but valid under the rule permitting one to sell his business and agree not to engage therein for at least a limited period.—Sauser v. Kearney, 126 N. W. (Iowa) 322.

Where a bond for the performance of a building contract by the contractor reserved to the surety the right to complete the building in case of an abandonment by the contractor, and the surety waived such right after abandonment on condition that the contract for completing the building should be let to the lowest of three bidders who should give a bond for the faithful performance of the contract, and the building on the abandonment of the contractor was completed under a special contract let to the lowest of three bidders, the provision in the original contract for auditing the expense of completion did not apply to the special contract.—Y. M. C. A. of North Yakima v. Gibson, 108 P. (Wash.) 766.

In altering the condition of his land adjoining another's building by excavating the soil and replacing it with a structure, the owner must not only abstain from collateral negligent or wrongful acts, such as unnecessarily heavy blasting, digging out the adjacent wall, projecting heavy articles against the wall or building, and the like, but must perform the work with reasonable care for the safety of the adjacent building, such as diligence in the construction of his wall after having removed the soil, removal of the soil and replacement thereof with the wall by sections, if necessary as a measure of reasonable precaution, or the adoption of other reasonable and practicable precautions.—Walker v. Strosnider, 67 S. E. (W. Va.) 1087.

If an adjoining owner, about to excavate along the side of a building belonging to another person, for the erection of a building on his own property adopt, as a means of protecting the building, the cutting of a trench and construction of a concrete retaining wall therein four feet from the building along the side thereof, and then running directly to one corner thereof, and let the work of cutting the trench and constructing the retaining wall to contractors, under contracts, leaving to them no discretion as to where or how such wall shall be constructed, and such measure of protection does not amount to the exercise of reasonable and ordinary care for the safety of the building, and, by reason of such neglect, the building falls, the employer is liable.—Walker v. Strosnider, 67 S. E. (W. Va.) 1087.

Shingles Required in a Roof.

To the square foot it takes 9 if exposed four inches; 8 if exposed 4½ inches, and 7 1-5 if exposed 5 inches to the weather.

Find the number of shingles required to cover a roof 38 feet long, and the rafters on each side 14 feet. Shingles exposed 4½ inches.

$28 \times 38 = 1{,}064$ (sq. ft.) $\times 8 = 8{,}512$ shingles. Ans.

To find the length of rafters, giving the roof one-third pitch: Take three-fifths of the width of the building. If the building is 30 feet wide, they must be 18 feet long exclusive of projection.

The average width of a shingle is four inches; hence, when shingles are laid, four inches to the weather, each shingle averages sixteen square inches, and 900 are required for a square of roofing.

If 4½ inches to the weather, 800 will cover a square.
If 5 inches to the weather, 720 will cover a square.
If 5½ inches to the weather, 655 will cover a square.
If 6 inches to the weather, 600 will cover a square.

This is for common gable-roofs. In hip-roofs, where the shingles are cut more or less to fit the roof, add five per cent to above figures.

A carpenter will carry up and lay on the roof from 1,500 to 2,000 shingles per day, or two squares to two squares and a half of plain gable-roofing.

One thousand shingles laid four inches to the weather will require five pounds of shingle-nails to fasten them on. Six pounds of four-penny nails will lay one thousand split pine shingles.

By the "pitch" of a roof is meant the relation which the height of the ridge above the level of the roof-plates bears to the span, or the distance between the studs on which the roof rests.

The length of rafters for the most common pitches can be found as follows from any given span:

If ¼ pitch, multiply span by 559, or 7-12 nearly.
If 1-3 pitch, multiply span by 6, or 3-5 nearly.
If ⅜ pitch, multiply span by 625, or ⅝ nearly.
If ½ pitch, multiply span by .71, or 7-10 nearly.
If ⅝ pitch, multiply span by 8, or 4-5 nearly.
If full pitch, multiply span by 1.12, or 1⅛ nearly.

Safe Heights and Lengths of Brick Walls.

For first-class buildings (the workmanship being good), as a general average the walls should not exceed a greater number of feet in height than three times their thickness in inches, and the length should not exceed double the height, without lateral support or stiffening by pilasters, buttresses or wing walls, say for

	Safe height.	Length should not exceed.
8½-inch walls	25 feet	50 feet
13 -inch walls	40 feet	80 feet
18 -inch walls	55 feet	110 feet
22 -inch walls	65 feet	130 feet
26 -inch walls	75 feet	160 feet

When the length must exceed these distances, as in depots, warehouses, etc., the thickness must be increased, or lateral braces provided (such as pilasters or buttresses) and at as short intervals as practicable.

Direction for Using Mortar Colors.

1. The mortar must be cold before mixing in stains, but do not let stain freeze if liquid stain is used.
2. Keep soft in package by covering with water, and pour off before using.
3. Work in your stain thoroughly to have your color uniform.
4. For very fine work strain your stained mortar though a fine sieve.

PROPORTIONS FOR STAINING MORTAR BY WEIGHT.

A fair average for staining mortar for 1,000 bricks: Fifty pounds red, Windsor, terra cotta, amber, seal, fern geen or salmon; 40 pounds buff, brown, purple, French gray; 26 pounds black. By measure, one bucket of stain to seven buckets of mortar.

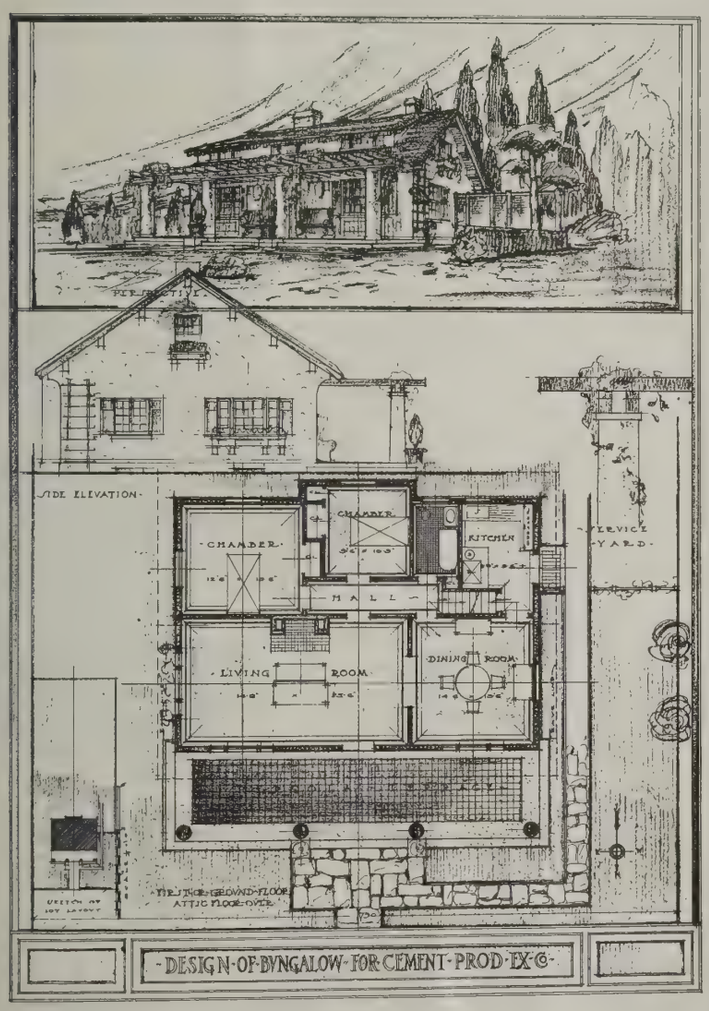
Facts Concerning Stone-Work, Brick-Work and Plastering.

STONE-WORK.

1. A cord of stone, three bushels of lime, and a cubic yard of sand will make 100 cubic feet of wall.
2. One cubic foot of stone-work weighs from 130 to 175 pounds.

BRICK-WORK.

3. Five courses of brick will make one foot in height on a chimney.
4. One cubic foot of brick-work with common mortar weighs from 100 to 110 pounds.
5. A cask of lime will make mortar sufficient for 1,000 bricks.



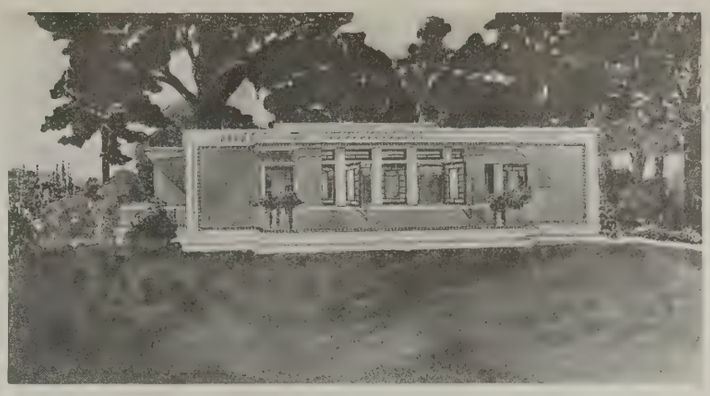
Walls laid up of good, hard-burned bricks, in mortar composed of good lime and sharp sand, will resist a pressure of 1,500 pounds per square inch, or 216,000 pounds per square foot, at which figure it would require 1,600 feet height of twelve-inch wall to crush the bottom courses, allowing 135 pounds as the weight of each cubic foot. It also appears from accurate calculations and measurements that walls laid up in the same quality of brick and mortar, with one-third quantity of Portland cement added to the same, are capable of resisting some 2,500 pounds per square inch, or 360,000 pounds per square foot; this would require a height of wall 2,700 feet to crush the bottom bricks.

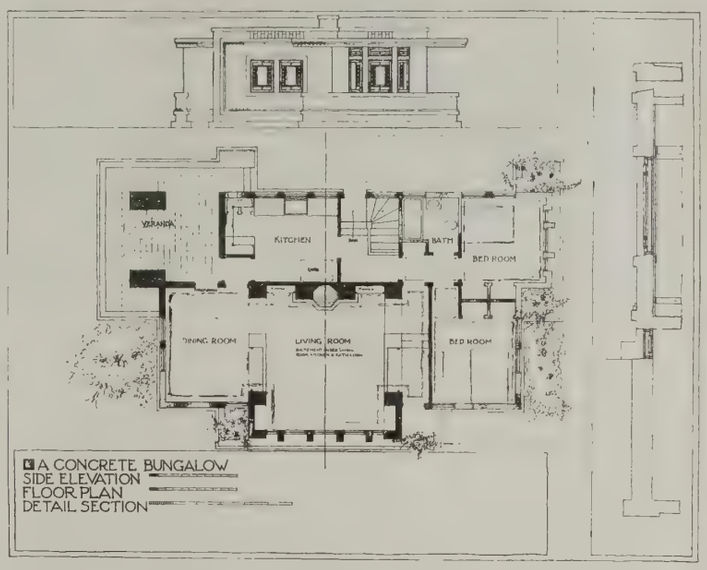
THREE CONCRETE BUNGALOWS

The competition for designing a concrete bungalow held by the Cement Products Exhibition Company, 72 West Adams street, Chicago, closed on Saturday, June 17. A great number of designs were submitted by architects and draftsmen from all over the country. The plans have been on exhibition in the offices of the Cement Products Exhibition Company for the past few weeks.

The jury of award in the competition, consisting of Messrs. Hugh M. G. Garden, Sam A. Marx and Walter Burley Griffin, all of Chicago, made their report on June 21. The jury recommended that the amount of the first three prizes be divided equally among three of the contestants whose designs were given equal rank and were in the opinion of the jury of equal merit. The prize money was distributed accordingly, $100 being given to each of the following:

Frederick J. Meseke, New York City.
F. W. Kerrick, South Bend, Ind.
Harry F. Robinson, Chicago.





Favorable mention was made of the bungalow designs submitted by the following:

Mr. Drummond, River Forest, Ill.
E. S. Sommors, Chicago, Ill.

The competition was considered successful in every way, both by the Cement Products Exhibition Company, and the jury.

The program of the competition called for designs for a bungalow to cost $4,000, not including heating apparatus, plumbing, electric wiring or fixtures. The competition was open to any architect or draftsman desiring to enter. The bungalow was to have at least two bedrooms and a total of not more than five rooms and bath. The program called for foundations of plain or reinforced concrete, hollow cement tile or plain concrete blocks. The exterior walls and interior partitions were to be of monolithic reinforced concrete, hollow cement tile or concrete blocks and cement plaster on metal lath or wire mesh was also permissible on the interior partitions.

The principal object of the competition was to secure a suitable design for a cement bungalow to be built for Mrs. Lucile Bishop of Chicago, who won the prize bungalow at the Fourth Annual Chicago Cement Show, February last.

TRADE REVIEW

ACETYLENE GAS LIGHTING.

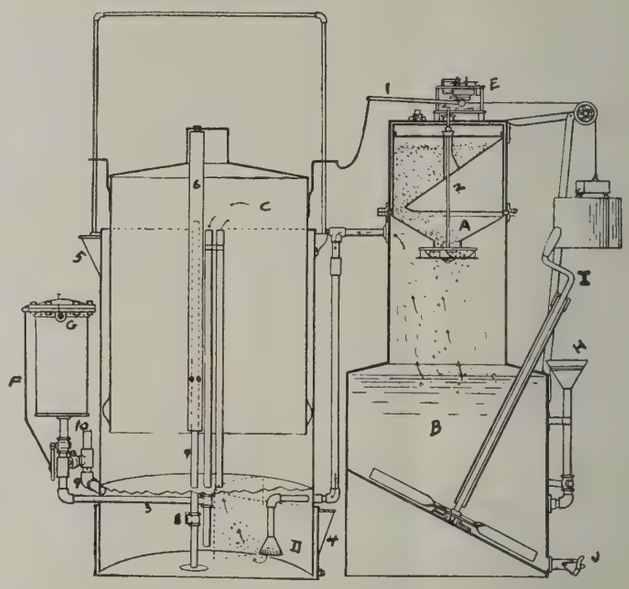
Farm life and the charm of the country is nearly always dimmed, literally and figuratively, by the quality of the lighting plants with which the buildings are equipped. Only a few years ago, candle light was about the only light, but there has been a vast improvement. Even the poorest now use oil lamps, and some, near cities and towns, can secure gas and electric lights.

To a great majority, however, the isolation of the farm house,

RESIDENCE OF W. J. BRYAN, LINCOLN, NEB., EQUIPPED WITH A DAVIS ACETYLENE GENERATOR.

and many village and town houses, precludes the use of either gas or electric light. To such the use of separate acetylene gas machines gives a lighting and heating medium superior to city gas or electric current, and at a less price.

Acetylene is a colorless, tasteless gas having a peculiar odor. It is generated from calcium carbide in a very simple and relatively small apparatus. Toy generators have been made no larger than a thimble, but for practical use, the generator and tank is about the size of a small stove. Calcium carbide, which is made by fusing coke and lime, needs only the addition of water to liberate the gas. The purpose of the generator, therefore, is simply to mix enough carbide with water to liberate the gas required. Connected with the generator as a rule is a tank to contain the manufactured gas, and to keep a



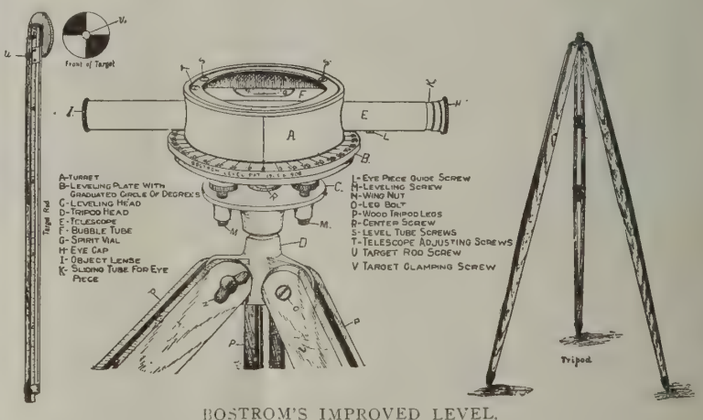
HOME AND SANITARIUM OF DRS. CROW & CROW, ELKHART, IND., EQUIPPED WITH A DAVIS ACETYLENE GENERATOR.

uniform pressure in the piping system. The piping system in the building is the same as for ordinary gas, except that only about one-fourth as much acetylene gas is required to produce the same light or heat as illuminating gas. For this reason the piping can be made smaller. The less gas consumed requires a special tip to the burner, but otherwise it is about the same in operation as the ordinary gas supplied in the large towns and cities.

Considerable apprehension has been felt regarding the danger of acetylene gas. There seems to be little warrant for this, as the limited amount of gas kept on hand, or which could be generated by carbide in the generator, would neither endanger the health of the occupants nor cause an explosion, In this respect it is far safer than ordinary gas, as the supply soon ceases while ordinary gas continues to flow as long as a jet is left open.

Installation of an acetylene plant is as simple as installing the gas piping in an ordinary house. The generator may be set up in the basement or other room where the water in it will not freeze. The generator is charged about once a week for a small house plant, the entire operation requiring only a few minutes.

The operation of the generator is well shown in the cut herewith. Various systems employ slightly different apparatus, but the principle does not vary greatly. The generating-chamber is shown on the right, the gas-chamber on the left. As gas is used the gas bell C gradually falls. When a certain level is reached the chain pulls lever 1 and trips the motor, which revolves shaft 2, plowing off a few lumps of carbide which fall into the water B as indicated.



Acetylene is immediately formed, which rises and passes through the pipe, as indicated by the arrows, and enters chamber D, which is filled with water, the gas bubbles through this water and enters the gas chamber through the pipe as shown. As the gas in so doing releases the lever 1. Thus gas enters the bell C, and raises it and checks the supply of carbide. It is thus seen that the generator is automatic in its action.

There are a number of concerns manufacturing apparatus for generating acetylene gas. One of the best known is the Davis Acetylene Company, 35 Prospect St., Elkhart, Ind. A postal to them will bring such information as may be desired.

BOSTROM'S IMPROVED LEVEL.

The expressed appreciation of our readers occasioned by our calling attention to all new and improved equipment which they require, encourages us to be continuously on the outlook for improved equipment possessing real merit, and any article must have real merit before we give it recognition.

Believing a clearer idea will be conveyed as to completeness, simplicity, accuracy and durability of the Bostrom Improved Builders' and Contractors' Levels, we have prepared a detailed illustration of one of these $25.00 outfits, which we here present.

BOSTROM'S IMPROVED LEVEL.

For builders and contractors, large or small, we unhesitatingly recommend the Bostrom level as possessing elements which meet the requirements to a greater degree than any other levels within our knowledge at a considerable advance over the Bostrom price.

The announcement of the manufacturers in this issue sets forth details and terms which should be at once investigated by all of our readers who are now in the market, or expect to be soon, for a thoroughly dependable level at moderate cost, such as Bostrom's Improved Level.

The Saw You Would Fight to Keep

Own a Saw, anyway.

The Expert Carpenter may have a half dozen saws.

The once-in-a-while handy man who likes to "fix things" about the place should own a good saw too.

The contractor should have a set of Simonds Saws.

Si-monds Saws
Made of Simonds Steel

Ask your Hardware Dealer for a Simonds Saw. You run no risk whatever in buying this saw. We take all the risk because we know we have the right saw and can do it.

But you don't want a saw that's merely guaranteed, one that you aren't compelled to keep. You want a saw you would fight to keep.

That puts the Simonds Saw in a class by itself. Once you buy and use it, you forget all about any guarantee. The saw is so good that you simply want to keep that Simonds Saw.

Simonds No. 8½ (see trade mark in illustration above) made of Simonds Steel, warranted, carved and polished apple handle, skew back, five brass screws in handle. Patented temper. Accurately ground. Hand, Rip or Panel. If your Dealer will not sell you this saw, we can send it direct from the factory. Send postcard for Dealer's name and price of saw you want. Give length, point, and whether straight or skew back.

THE JACKSON ALUMINUM LINE LEVEL

Is designed particularly to meet the requirements of all Mechanics in building construction, especially Bricklayers, Masons, Carpenters, Millwrights, Architects, and Cement Workers.

By using the Aluminum Line Level you can take Levels in one-half the time required by the old method of the Straight Edge.

This is possible because the Aluminum Line Level weighs only one-fourth ounce and is easily and quickly attached to a line. Levels thus taken are guaranteed to be accurate on a stretched line from one to forty feet. Besides, from its construction, it can be used as a Pocket Level.

This cut shows the Aluminum Line Level, including Attachment and 40-ft. line. Complete in Leatherette Case.

PRICE $1.00, POSTAGE PREPAID

It is especially adapted for laying out foundations for buildings. It will do the work no other level will do. For sale at hardware dealers, or

SYRACUSE CORNER BLOCK FACTORY,
SYRACUSE, NEW YORK

HOLDING THE DOOR OPEN.

Many times it is just as desirable to hold the door open as to keep it closed. A door check will close a door gently and keep it closed against ordinary wind pressure, etc., but they will not hold the open when required. Hotels, ball rooms and public buildings all have occasions when some one must be stationed to hold the doors open for a few minutes or several hours at a time.

The Caldwell Manufacturing Company of Rochester, N. Y., have just put on the market a very neat and effective device for holding a door ajar at any desirable point. The device consists of a slightly bronzed bolt, having a rubber bottom attached to the lower end, which by a spring—adjusted by the foot—holds the door in place. There is only one screw-head visible in the bracket which holds the device in place. The illustration shows the little attachment, and is about the same size as the article itself. It is not at all obtrusive or unsightly, as it is oxidized and not unshapely. It is held down, or released at will by the foot, and the rubber end presses against the floor and holds the door in position, no matter how smooth or polished the floor may be, and no injury is done the floor no matter how often the bolt is used. This device will be found very convenient for many places and will be as useful for carpeted as for bare floors. Further particulars as to price and styles may be obtained by addressing the company as above.

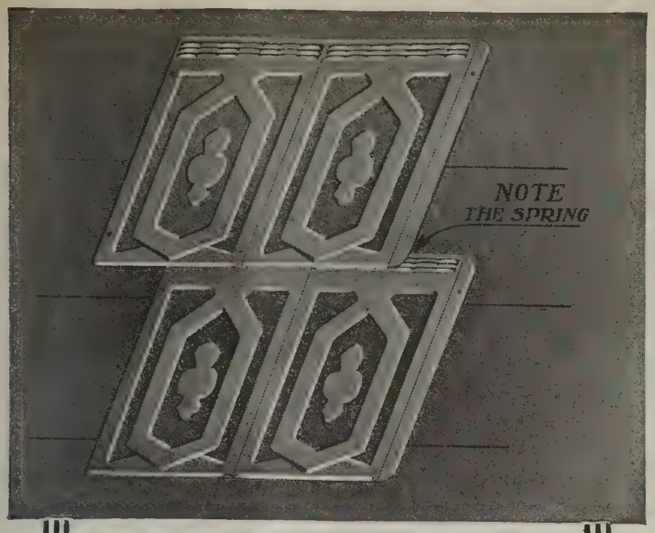
PLANNING AND BUILDING A HOME.

Who has not hesitated at the thought of the multitude of details to be considered, and at the result of a possible error in calculation, not so much perhaps at the danger to the stability of the building as to the increase of cost. Everywhere we see instances of buildings costing more than calculated, because not properly planned and thought out in detail, until it has become a by-word that the cost always overruns the highest estimate. The question arises—how much can this be cut down by careful planning?

But let us suppose that the plans and specifications are complete; that the owner understands exactly what he is to receive; and the contractor knows just what he must deliver. The building starts, and for a time all goes well—the local yards can supply plenty of the raw material, such as brick, stone, sand, cement, etc., but suddenly comes the need for frames, lumber, etc. Unless the contractor has been unusually forehanded there is a tedious delay reflecting on the business ability of the contractor. Too frequently these delays hold up the entire work until the arrival of a few pieces of material overlooked in the ordering.

If it were possible for the building contractor to foresee and to prevent the vexatious delays that are constantly occurring in the

DOOR DEPARTMENT. CAPACITY, 1,500 DOORS A DAY.



arrival of many shipments of materials and supplies, he would not only preserve his reputation, but there would be fewer disappointing discrepancies between his estimates and the actual costs of his completed contracts.

A high degree of that efficiency for which manufacturers in every line are striving today is impossible in the management of any contracting business unless careful account is taken of the enormous waste represented by time lost in waiting for deliveries of supplies and steps taken to eliminate this waste. Many a building job that was figured to net a fair profit has yielded the contractor a substantial loss instead solely because of delays on the part of his supply dealers to get his materials to him as needed. Many a contractor dares not undertake more than one job at a time because so much of his own time must be spent around freight depots and in writing letters and telegrams while his workmen must make such progress as they can without his personal direction and the aid of his expert knowledge.

The builder whose business is large enough to warrant his employing one or more men for the sole task of following up orders for supplies and seeing that the materials are shipped promptly and delivered according to a specified schedule has an advantage that his less prosperous rival cannot overcome while he is obliged to attend to that important detail in person.

Many builders have not the time to present to their clients their ideas concerning planning and construction. For a house costing well up in the thousands, the services of an individual architect are neces-

If it isn't an Akron it isn't the best Level

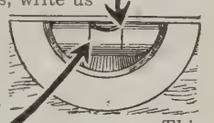
If you've never used an Akron you don't know what it means to use **the world's best level.**

You can tell instantly whether or not it's an Akron, by two exclusive features—the Akron double spirit-tube and the Akron "quick finder."

The Akron Spirit-Tube consists of an inner tube of clear-as-crystal glass set in an outer tubing of heavy steam-gauge glass with rubber bearings between. This makes a tube that is practically unbreakable—one that never breaks with the falls and jars incidental to daily use.

The Akron "Quick Finder" is two fine silver lines around spirit-tube, one at either end of bubble when it is exactly centred. The workman can read an Akron level quickly, at any angle, with absolute accuracy even in a very dim light.

AKRON ECLIPSE LEVELS



Made in 33 styles and sizes for carpenters, masons, concrete men and everybody who uses a level. Some are brass bound, some made with two plumbs, but all have the "quick finder" and double spirit tube. They cost no more than the ordinary kind, but they last longer.

See those 2 lines around spirit-tube?

Sold by Hardware Dealers Everywhere

If your dealer does not sell Akron Eclipse Levels, write us for catalog, mentioning dealer's name. Mail orders will be filled direct at lowest retail price where there is no Akron dealer.

This quick "finder" shows L-E-V-E-L or otherwise, instantly

ASBESTOS "CENTURY" SHINGLES

"THE ROOF THAT OUTLIVES THE BUILDING"

Asbestos "Century" Shingle Roof—Stable, Theodore M. Davis, Newport, R. I.: Architect, Theodore Davis Boal, Washington, D. C.; Contractors, Simpson Bros., Corp., Boston, Mass.

For the sake of your building investment ask these four questions about every roofing material

1. What protection does it give the building from fire, weather and time?
2. How long will it last?
3. Will it need repairs and painting?
4. What does it cost, including UP-KEEP CHARGES?

And remember this, Asbestos "Century" shingles are the only TRULY indestructible roofing known to the building trade. Made of REINFORCED CONCRETE. They are fire-proof, time-proof, weather-proof.

You can get Asbestos "Century" Shingles in shapes to suit any architectural style—in several sizes—and in three colors: Newport Gray (silver gray), Slate (blue black), and Indian Red. Ask your representative roofer about this indestructible roofing—or write us. Send for booklet "K. & M. 1911." It will settle your roof problems to your great satisfaction.

Everybody interested in a Material for Roofing and Siding Buildings should have them, because they show exactly the reasons for the great success of

READY-TO-LAY **Burmite**
(Reg. U. S. Pat. Off.)

FLEXIBLE-CEMENT-BURLAP INSERTED **MATERIAL**
for Roofing and Siding

These samples are not cut from material made up especially for advertising purposes, as is so often the case—they represent the exact weight, lasting qualities and artistic appearance of "Burmite" as it goes out from our plant every working day of the year, in the two separate surfaces, i. e.,

BIRD-SAND and "Twolayr" SLATE-CHIPS
(PATENT PENDING)

Recognized and acknowledged to be the most Durable, Practical and Inexpensive for use on Buildings of any kind of construction. **Guaranteed for 10 years without Coating,** and if properly laid will last from 20 to 25 years. **"Burmite" lasts longer than shingles—costs less, lays smoother, looks nicer and requires no paint to preserve it. Can be laid over old shingles or tin;** is odorless, will not "run" on steep roofs; and on account of its unusual flexibility, is especially well adapted to flat or uneven surfaces.

Used in any climate, can be applied in cold or hot weather without danger of buckling, expanding or contracting.

WRITE TODAY for Samples and Booklet,

"Burmite Quality Counts"

illustrated with buildings printed in colors showing beautiful effects of "Burmite" applied as a Roofing and Siding on Residences, Cottages, Summer Homes, Bungalows, Garages, Barns, etc.

sary, as the owner has his own ideas concerning arrangement, which would not be of interest to another owner. To many others, economy is a necessity and the greatest economy can be exercised by using one of the standard plans, on which a large amount of individual architectural work has already been expended with a view of utilizing all the space, regular lengths of material, standard sizes of doors,

A CORNER IN SASH WAREHOUSE. 100,000 WINDOWS, GLAZED, READY TO SHIP.

windows, trim, etc. With such a plan it is possible to list the materials required with great accuracy, so that the assembling and shipping is greatly facilitated.

Minor changes in plan or construction can easily be made, adapting each plan to the individual taste of the owner, at the same time causing no delay in getting out the material.

There are advantages in purchasing the bulk of the material from one concern. When properly listed fewer mistakes in packing, marking and shipping are made, and the material filling one or more cars goes forward with few delays and without danger from loss through transshipment. Sufficient material is always on hand, so there are no delays from lack of material.

A concern catering to the building trade in this manner is able to keep a sufficient supply on hand to fill all orders, thus giving exceptional service to each individual case. The quantities for which a large concern can place orders insures a flexibility through standardization which cannot be obtained in individual orders.

SHIPPING DEPARTMENT NO. 1. ESPECIALLY EQUIPPED FOR HANDLING CARLOAD ORDERS. CAPACITY, TWENTY CARLOADS A DAY.

The plan followed by Sears, Roebuck & Co. provides the contractor or owner with the services of architects of the highest ability in the design of economical buildings. The service is without cost and can be only obtained when used in conjunction with a large concern such as this. Briefly, the plan is as follows: The intending purchaser secures a copy of the Book of Modern Homes, which is sent free by writing to Sears, Roebuck & Co., Chicago, and mentioning the national builder.

The Book of Modern Homes is the product of the best skill of a corps of high class architects employed by Sears, Roebuck & Co. and contains pictures and plans of nearly a hundred bungalows, houses and cottages of every modern type, adapted to the requirements of every climate, and embodying all the newest ideas in home building. The intending buyer, having selected from this handsome book the house he desires to build, has only to send a dollar to the firm to receive a complete set of blue prints, specifications and bill of materials. (This nominal charge of $1.00 is credited upon the customer's first order for materials.)

A new feature of the builders' supply service lately perfected by Sears, Roebuck & Co. is designed to afford a complete solution of

this aggravating problem. It provides that every order for a bill of house materials shall immediately on its receipt be turned over to a trained order man, who becomes virtually the customer's personal representative in the house, being charged with the duty of following through the warehouses and factories every item included in the order and seeing to it that the materials are laid down at the contractor's freight depot promptly as needed and in perfect condition. The tracer's responsibility extends to every article included in the bill of materials, from lumber to paints and varnishes.

Among those who have not followed the remarkable growth of building supply business of this firm much wondering comment has been caused by its advertisements appearing in current issues of the national builder.

Through the editor, the company offers the explanation that no advertisement, or series of advertisements, can give more than a suggestion of the almost unlimited service they have organized for the benefit of the builders. Only an examination of the Sears, Roebuck & Co. building material and millwork catalogue can give an adequate idea of the variety and extent of its stock and manufacturing facilities.

In more than a score of factories which it either owns outright or whose entire output it controls, this great merchandise institution produces every kind of building material required in modern construction work, excepting only brick, plaster and cement, and not forgetting to include gasoline engines, wood working machinery, carpenters' tools and concrete block making machines.

A condensed list of builders' supplies manufactured and sold by Sears, Roebuck & Co., being priced in every instance at the actual cost of making, plus one single profit, embraces the following:

Dimension and finishing lumber, including flooring and siding, shingles, etc., in all suitable woods, shipped from great lumber yards

SHIPPING DEPARTMENT NO. 2. ESPECIALLY EQUIPPED FOR HANDLING LESS THAN CARLOAD ORDERS. CAPACITY, TEN CARLOADS A DAY.

in the central west or from their southern mills adjoining the choicest timber lands in the country.

Mill work of every description, manufactured in a plant modernly equipped and with facilities for shipping 1,500 doors, 3,000 windows and other materials in same relative quantities during one working day.

Roofing of felt, asphalt, flint coat and corrugated steel.

Bathroom fittings and plumbing goods of all kinds.

Paints and varnishes, wall paper, mantels, wood, tile and brick, consoles, metal ceilings, tile floors and walls, builders' hardware, art glass windows, parquetry floors, ornamental fencing, lighting fixtures, electrical goods, lightning rods and pumps.

By means of lot numbers every piece of material is easily checked from the blue prints against the bill of materials and the catalogue and wherever any minor change in the plans is desired by the builder he has only to substitute other materials by selection from the catalogue. Thus the finished building will express, when completed, his individual tastes, ideas and preferences to the last detail, at the same time including in its design and construction every improvement sanctioned by the most skillful architects and the best informed builders.

The reader is reminded that the foregoing is merely an outline of the plan under discussion. To secure further information, it is only necessary to write to Sears, Roebuck & Co., Chicago, Ill., mentioning the NATIONAL BUILDER, and the fullest information can be secured, as well as the Book of Modern Homes.

The Ideal Engine for Shop Power

Schmidt Bros. Co. Engine Works, Dept. 697X, Davenport, Iowa

EVERY CONTRACTOR

LARGE OR SMALL WOULD BUY A

Bostrom Improved Builder's Level

If he would just drop us a line to ship him one for inspection and approval. We say that because we have never known a Contractor, Builder, Architect, Surveyor, Civil Engineer, or even Instrument manufacturer to inspect a BOSTROM LEVEL who did not concede that at the price there had been nothing yet produced which would compare with the Bostrom in all the necessary essentials of a simple, accurate, durable and throughly dependable Level

Another thing, the Bostrom Level possesses means of adjustment for proving its accuracy, not surpassed by the highest priced Engineer's Level, and this principle is applied in such a novel and simple manner that even the inexperienced operator can **prove his work right on the spot,** and it can be done in a mere fraction of the time required to prove the accuracy of any other level, regardless of the price.

You have to examine the Bostrom Level to appreciate all of its merits, but the above feature alone makes sales on sight, and a sale always means a Bostrom endorser.

We back up every statement we make with a GUARANTEE of satisfaction or money back.

Our terms are cash with order, or shipment made C. O. D. SUBJECT TO EXAMINATION. Prices: No. 3, $25.00; No. 4, $30.00, f. o. b., Atlanta. Shipping weight 15 lbs., and complete outfit includes Level, Tripod, Graduated Hardwood Rod (not furnished by any other manufacturer without extra charge), Target and Plumb-bob, Trivet, and neat oak box for keeping Level when not in use. Eyepiece in No. 3 Telescope has magnifying power of 10 to 12 diameters, with sliding focus; and eyepiece in No. 4 Telescope has magnifying power of 18 to 20 diameters, with rack and pinion focus.

If you are needing Level at once, order direct from this article, as we do not even require you to guarantee express charges (and no other instrument manufacturer ever made such an offer). We don't hesitate to do it, as we have shipped thousands of Levels in that manner, and the enthusiastic endorsements of these purchasers gives us the unlimited confidence that the Instrument will please you. If you are not needing Level right away, write for full description and get acquainted with the Bostrom before buying. Bostrom's Levels are used and endorsed in every State in the Union, and are rapidly taking the place of instruments much higher in price, and you owe it to yourself to inspect the Bostrom before buying.

Cassens Ideal Eaves Trough Takes Water Only

The Ideal completely overcomes the disadvantages of the old style open gutter. It satisfactorily catches and carries away the water that falls on your roof. Its use insures clean, healthful cistern water. Leaves, trash, gravel, etc., cannot enter it. Neither can birds build nests in it. Therefore it is never clogged. Ice will positively not break down the trough

A unique and important feature of the IDEAL is that it will not fill with snow and ice. When it sleets the small opening (about one-eighth inch) is quickly closed. This prevents the bursting of the trough, also of the down spout. When it thaws the ice melts, and the entrance opens automatically before the water from the roof reaches it.

The Ideal can now be erected with a Wire Hanger if face-board has mouldings.

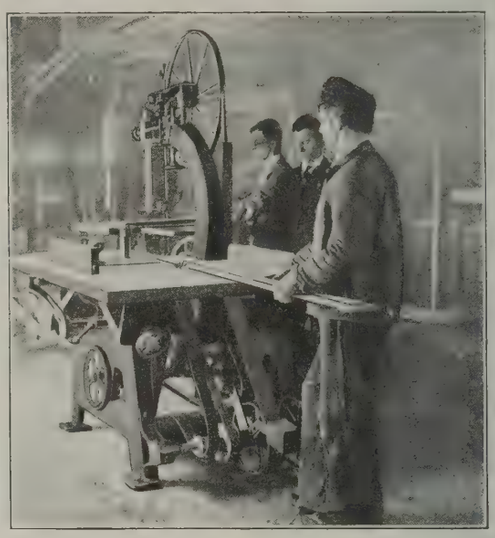
EXTENSIVE ADDITIONS.



We are pleased to learn that the Niagara Falls Metal Stamping Works are compelled to again enlarge their plant. For the third time in seven years they find their shops too small to accommodate their increasing business.

The new buildings now under construction will give them a basement 60x100 feet with ample headroom for new and heavier machinery, as well as a large fireproof vault for storing dies.

By the latter part of August their new plant will be in operation and they believe that it will be one of the best equipped in the country for specialty jobs.

TANGIBLE PROOF OF WOODWORKER EFFICIENCY.

We want to call the attention of those carpenters, builders and contractors who desire to quit making planing mills rich, to the letter and illustration reproduced below. It tells graphically how one contractor got a complete machine shop when he installed one machine, and how his every requirement has been met and satisfied.

Ogdensburg, N. Y., April 20, 1911.

The Sidney Tool Co.,
Sidney, Ohio.

Gentlemen:

By this mail I am sending you a picture of the No. 20 Universal Woodworker that I installed this winter. It is without exception one of the finest and most compact machines of its kind on the market.

One of the most desirable features is that I can work three men at one time without interfering, as the picture shows. The work I have to do is the heaviest kind and have found that the machine will stand up under severe strain and also do the finest work and at the same time occupies very little floor space.

I certainly recommend this machine to any one needing a first class woodworker. Thanking you for the courtesies shown in the past and trusting to be able to be of some service to you, I remain,

Respectfully yours,

CHAS. C. IVES.

The machine referred to in above letter was the famous Universal Woodworker, built by the Sidney Tool Co., Sidney, Ohio, who inform us that over six hundred of their woodworkers are in use, and that not one has ever been returned for repairs.

Their No. 14 machine, which they claim is a special favorite among contractors, embodies the qualities of sixteen individual woodworking machines, and performs each class of work as good as a machine built expressly for doing only one kind of work.

To read the foregoing a person's imagination would conjure up a machine very complicated, very delicate and very difficult to understand. But, strange to say, the reverse is the case. The principle of construction is so unique that complicated and delicate parts are conspicuous by their absence. As a matter of fact, there is practically nothing about the machine that could break down or cause trouble in any way. In operation it is so simple that any machinist possessing a rudimentary knowledge of woodworking machinery can operate it with ease. The bare fact that out of the six or seven hundred in use not one has ever caused the least trouble, is sufficient evidence of its durability.

It costs nothing to get full particulars of this remarkable machine if you mention THE NATIONAL BUILDER. The Sidney Tool Co., Sidney, Ohio, state they will be extremely glad to answer any question concerning it.

NON-BREAKABLE LEVELS.

The value of a level is determined not so much by the cost of the materials that are used in its making as by its wear-resisting and fall-resisting qualities.

In this regard the Akron Eclipse Level no doubt excels all others, for its double spirit tube is practically unbreakable. It will stand the falls and jars incident to daily use without the least danger of breaking. In Akron Levels the spirit tube proper is encased in an outer tube of heavy steam gauge glass, with rubber bearings between the tubes. Then the spirit tube is suspended in the laminated wood frame by two brass arms, making it far less liable to break than any ordinary level.

Another exclusive feature of Akron Levels is the use of two fine silver lines around the spirit tube, one at either end of the bubble, to define the exact center. This leaves nothing to guesswork

Build Artistic Stairways From Gordon-Van Tine Stock!

Save 50%! Special Millwork Catalog FREE

Our Stair Department Will Save You Big Money

Through our ceaseless efforts of selling reliable stairwork at cost plus one small profit, we have been able to produce and sell stairwork at prices which leave a handsome profit for the contractor. In our Grand Free Millwork Catalog we itemize individually, each and every article required for the stairs, and explain fully just how this material comes to you and attach net prices. With this information at your command, an infinite variety of arrangements of stairs can be figured within a few moments, and you know the exact cost without entrusting your interest to any outsider.

A Flight of Stairs Complete for **23.93**

The fact that part of this material is already machined ready to go right into the stairs, reduces the erecting cost very materially. We use only thoroughly kiln-dried material in making up the different parts of this stair stock, and only the most skilled and expert mechanics are employed in the production of the finished article. By using kiln-dried lumber you avoid any of the annoying effects of shrinking or coming apart of the stairs after they are put in the building. The itemized list for a flight of stairs which is given on this page, shows you at a glance how reasonable the material for a complete stairs can be purchased.

The fact that you have had no previous experience in the stair building line should not deter you one moment from learning its simplicity now. If there are any points which are not practically clear to you regarding the proposed stair for which you are in the market, write us, and we will give you the advice of an expert stairbuilder.

Vast Assortment of Oak and Yellow Pine Stair Material

Our stock designs of Stair Newels, Rails, Balusters, Steps, Risers, Face and Wall Stringers and miscellaneous materials in Oak and Yellow Pine is very complete. A line which is at once adapted to the swell and modest cottage or most elaborate home.

Correct in Every Detail

We call particular attention to the style of construction, for instance, of our posts; the correct size of all mouldings, in order that the assembled effect may be harmonious and complete. Likewise, the turning of the balusters and shape of rails are especially adaptable for these specific purposes.

With the styles illustrated, an infinite variety of arrangements of stairs is permissible, and it is a very rare exception when special work will be required for any particular purpose. Our designs are modern and up-to-date. All Newels are hand smoothed and made from thoroughly kiln-dried stock. All carvings are handmade and not composition ornaments. Every Newel from one-inch lumber, with glued lock joint. Height of all starting Newels 4 feet, with 8x8 base and 6x6 shaft, suitable for open or closed stringboard. Base of post, 20 inches long, allowing one or two risers. Every Newel wrapped in paper and carefully packed. The stock is all thoroughly machined, well kiln-dried and can be shipped promptly.

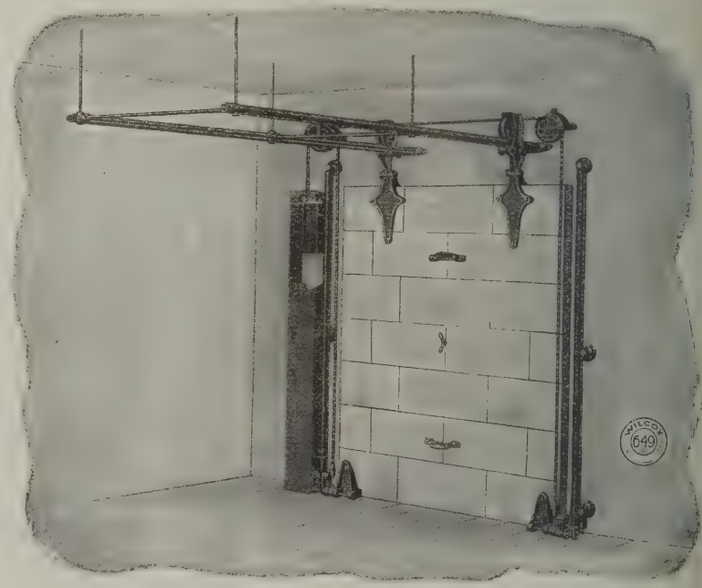
and makes it possible to read the level in any position and even on a dull, cloudy day. Akron Levels are made by the Baker, McMillen Co. of Akron, Ohio, who are pioneers in the level industry of America, and have undoubtedly done much to bring the spirit level up to its present state of efficiency.



A catalog of Akron Levels and full particulars may be obtained from the Baker, McMillen Co., Dept. A, Akron, Ohio, mentioning THE NATIONAL BUILDER.

RICHARDS-COLBY HORIZONTAL TROLLEY DOOR FIXTURES.

The Richards-Wilcox Manufacturing Co., Aurora, Ill., are offering the "Wilcox-Colby" Horizontal Trolley Door Fixtures. Builders frequently have doors to hang where the headroom is not sufficient for vertical doors and obstructions prevent the use of regular sliding doors.

This device is also provided with an automatic fusible link device for tin-clad fire doors. The simplicity and ease of operation make this a desirable proposition. We suggest our many readers, if interested, write the above company regarding this "Wilcox-Colby" device and in writing mention THE NATIONAL BUILDER.

6 Months' Free Trial

Hand and Foot Power

Mechanics' Special—will not draw temper

Don't take our word that this tool grinding, buffing and polishing outfit will save money for *you*. We offer you 6 months' absolutely *free use* of this outfit in your own work on your own tools, and let you prove for yourself that it is a money-saving and money-making outfit for any tool user. Use it a whole half year free, and if you don't find it a money-maker for you, send it back. The half year's use will not cost you a cent. If you want to make your own work and the work of the men you hire count for the most profits, how can you neglect this liberal offer? Return the coupon at bottom of page for 6 months' free trial offer.

Luther Tool Grinders

6 times faster than emery wheels
25 times faster than grindstones
Built like a high grade lathe

Special attachments enable inexperienced persons to sharpen Chisels, Twist Drills, Etc.

The genuine Carborundum wheels will not draw temper from tools; no need of cooling with water—all your tools will last longer, which means that much money saved. The wheels cut hardest steel as emery does soft copper—it is only a moment's work to do any job of tool sharpening, so easy in fact that tools are always kept razor-keen and that means more work accomplished with less effort, which means more money saved. The wheels outwear any number of emery wheels and that means another money-saving.

11 Tools in One

consisting of Mechanic's Special, built like a high-grade lathe, with steel and malleable construction, machine cut spur gears, bronze bearings in oil bath, etc., and the following accessories: rough Carborundum wheel, fine Carborundum wheel, 1 chisel attachment, and 1 twist drill attachment by which inexperienced persons can sharpen chisels and twist drills, 1 polishing spindle, 1 buffer, 1 polisher, 1 oil stone, 1 Carborundum hone in leather case, 1 Carborundum scythe stone, 1 foot-power attachment.

Return this Coupon for 6 Months' Free Trial Offer

This perfected sharpening, polishing and buffing Mechanic's Special Outfit is a business and labor economy—can you afford to neglect our liberal offer? Return this coupon for 6 Months' Free Trial Offer, and free booklet reprinting the story of Carborundum as it appeared in McClure's Magazine.

IS A MOTOR DRIVEN VEHICLE A GOOD BUSINESS INVESTMENT FOR CONTRACTORS AND CARPENTERS?

We have been asked the above question so often by our subscriber friends that we are led to believe that at this time an open statement will be more or less timely. This is an age of speed. It makes no difference the line of business one may be in. There is always competition. The "low man" (price and quality being the same) always gets the work. To be "low man" necessitates careful figuring and low cost. Contractors

who have under way several pieces of work often find they are unable to adequately superintend the construction of a number of different jobs, especially if they are all scattered. Inadequate superintendence always means more or less mistakes, etc. To this kind of a contractor a motor driven vehicle is almost a necessity. The day has passed when an annual small contract or so would provide sufficient remuneration. Today the contractor must have a number of contracts. The more he can handle the greater his profit. It is almost impossible to specify at all clearly just what contractors it would pay to invest in a motor driven vehicle. This depends on the amount of work in hand, the amount of the original investment in the vehicle and the "up-keep." Perhaps the most generally used of these motor vehicles is the motorcycles. It supplies the owner with even greater speed in "getting about" than an automobile, and the "up-keep" cost and original investment is much smaller.

The writer recently talked with a contractor who used such a machine in his work and he stated that he would be lost without same. Out of curiosity he had figured the maintenance of his machine and found that same amounted to about one-eighth cent per mile traveled. This, of course, is much less than even street car fare. The machine he has is a "Harley-Davidson," made in Milwaukee, and is equipped with a luggage carrier, which enables him to carry bundles or packages, not exceeding 200 pounds in weight. He further states that many contracts have been secured by him through his ability to get to see the prospect. It is but a few moments' work for him in the evening, and pleasant work at that,

to run a few miles and call upon the prospective builder. Of course, this same service could be obtained with the aid of an automobile. One large contractor who owns an automobile has told us that his automobile has more than paid for itself and its "up-keep." We do honestly believe that a motor driven vehicle of some sort would pay a handsome dividend to every contractor. It certainly is a matter worth looking into.

The above photograph was taken of a private dwelling near Wauwatosa, Wis., which was demolished by an explosion of gas. The roof is supported only by the center partition. Although the sides of the house were peeled off like card board by the force of the explosion, the windows in the attic are not even cracked. The writer and friend were on the scene ten minutes after the explosion, thanks to their Harley-Davidson motorcycles.

Henry Danielson, a prominent contractor of Milwaukee, originally used an automobile almost entirely for getting around in his work. Finding that a motorcycle was much less expensive he changed to a motorcycle and found that it was altogether more desirable than the motor car. Any of our subscribers who are especially interested, should write to the Harley-Davidson Motor Co., 707 L street,Milwaukee, Wisconsin, and get in communication with contractors who can give them more information regarding this subject, than herein given.

NEW METAL WORK CATALOGUES.

The Empire Iron & Steel Co., Niles, Ohio, are making advance announcement to the trade of two new catalogues showing their products.

The first contains upwards of fifty elegant half-tone illustrations of cornices and skylights, with appropriate descriptions and other information regarding this class of work.

The second catalogue comes from the Ceiling Department, and calls particular attention to ten new ceiling dies which have recently been added to their former large equipment. These ten designs are particularly prepared for "The Empire" in French Renaissance, Colonial, etc.

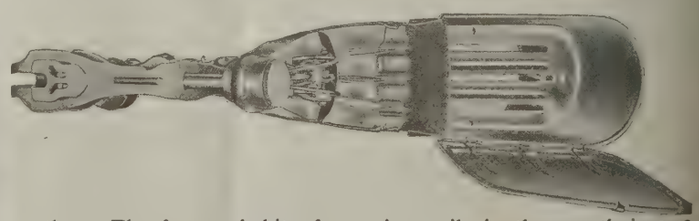
These art catalogues will soon be ready for distribution, and we are advised that copies of either catalogue will be sent immediately on publication to those mentioning THE NATIONAL BUILDER. As the demand will undoubtedly be large, it is suggested that requests for catalogues be made at this time.

HOT WEATHER TOOLS.

With the first day of warm weather the Editorial Department of THE NATIONAL BUILDER received from the Simonds Manufacturing Co. what appeared to be a box of fine cigars. The illusion was perfect, but a close inspection revealed the fact that the present was Japanese fans, which opened into a close representation of a buzz-saw. The pleasure of using these fans is the same as is supposed to come from the use of other tools bearing the Simonds name.

We understand that the mention of THE NATIONAL BUILDER to the Simonds Manufacturing Co., Fitchburg, Mass., will bring one of these beautiful presents.

A UNIQUE SIGNATURE TRADE-MARK.



FOX MACHINE'S CO.'S products are too well known to readers of THE NATIONAL BUILDER to require any particular mention at this time. The value of a trade-mark is a subject of much discussion, but it is conceded that it has a value in calling attention a particular gods and names. In this case, the Fox Machine Company has an ingenious method of signing their name, as shown at the head of this item.

The use of a symbol of this character, which is so perfectly adapted to the firm name, goes a long ways toward impressing the name on the public. It is the unusual which always attracts attention, after which there must be real merit in order to be of value. The Fox Machine Company have long been known as the manufacturers of the Fox Universal Wood Trimmers, and to keep their name before the users of carpenters' tools are sending a neat souvenir button bearing their trade-mark. We understand that this unique ornamental button will be sent free by the Fox Machine Co., 26 N. Front St., Grand Rapids, Mich., if THE NATIONAL BUILDER is mentioned.

SHINGLE NAILING MACHINES.

When one mentions driving nails by machinery the thought instantly arises that there must be a cumbersome apparatus necessary to do all that the human hands do in picking up a nail, holding it until the first blow of the hammer starts it, and finishes it with a harder blow. Is it possible a two-pound machine, so simple it can really be called a tool, can take the place of the hand and do the work well? That it is possible is answered by the thousands of Pearson Nailers in steady use.

The Pearson Improved Nailer can be used on a roof of any pitch. Its use allows the operator to wear gloves or mittens during severe

weather. The former habit of carrying nails in the mouth is also discontinued, as the nailer contains a pocket for several pounds of nails.

The cut herewith shows a top view and section of the nailer, showing the device for selecting the nails and getting them down to the plunger which sets them.

But the only way to really know this tool is to own one. The next best is to write to the Pearson Manufacturing Co., Robbinsdale, Minn., and by mentioning THE NATIONAL BUILDER, full information will be sent free.

Amatite ROOFING

Why the buyer of Amatite never complains

When a man buys ordinary ready roofing he usually neglects to paint it, and after three or four years he comes back to the dealer with a protest. It is human nature to neglect painting roofs

When a man buys Amatite Roofing he lays it on his building and in three or four years it is still as good as new and does not need any paint. He forgets he has such a roof, but no harm is done by that.

There is nothing to neglect in the case of Amatite. Amatite has a peculiar surface—a sort of plastic concrete made of pitch and mineral matter.

This surface is plastic enough so that the material can be rolled up into handy rolls in the usual manner and handled just like any other ready roofing. When unrolled on the roof and nailed down, it presents to the weather a continuous surface of mineral matter and pitch. On this surface wind, rain, storm heat and cold have little effect. Year after year it looks up to the sky undisturbed and unaffected. It costs nothing to maintain and relieves the owner from all responsibility.

Dealers can improve their business by selling Amatite, and buyers make a good bargain when they buy it. The price of Amatite is less than that of most painted roofings of less weight and durability.

Sample free on request.

S. C. Johnson & Son, Racine, Wisconsin
"The Wood Finishing Authorities"

ORNAMENTAL GRILLES

When there is a place for a grille in the house, there is every reason why the design and finish should harmonize with the rest of the furnishings. How often we find a grille perfectly suited to a log cabin or summer house doing service in a mansion. It is not a question of expense so much as knowing that grilles can be had to fit any opening, and to harmonize with any style of ornament. At the head

of this article we are able to show an excellent design from the No. 16 catalogue of the Northwestern Grille Works, 1824 Milwaukee avenue, Chicago, Ill. The same company also make an excellent line of mantels, consoles, etc., of new and original design. The bookcase and mantel shown herewith is an excellent substitute for the antiquated fireplace so often seen in modern homes.

We are advised that the mention of THE NATIONAL BUILDER will secure one of these beautiful art catalogues for those interested.

STAY LOCKED COLUMNS

The manufacturer of any article of wood intended to be exposed to the weather requires the consideration of the severest exposure to which the finished product will be subjected. After the work leaves the shop it is too late to find that it is going where it is subject to severe rains, fogs, dampness or dry, hot weather, or perhaps a succession of other unfavorable conditions. We say unfavorable—perhaps we should say severe—conditions, for if the work stands, it cannot be called unfavorable.

Possibly no part of the building is more exposed than the porch columns, or pergolas. Through sun and storm they must not only retain their strength, but their appearance and dignity. Weather joints, cranks, warping, swelling and shrinking are all forbidden in good work. But the question is, how can we prevent all these disfiguring effects of the weather?

In the manufacture of the Stay-Locked Columns the American Column Company of Battle Creek, Mich., claims to have reached the practical limit of perfection. Not only is the joint locked and glued,

PASTE THIS DOME ON LETTERS THAT YOU WRITE ADVERTISERS. IT WILL HELP.

but by a patented method they are able to join the separate staves with steel staples driven in after the column is glued up.

As practically all the art of the ancient Greeks and Romans was based on the proportions and appearance of the columns, how neces-

sary it is that the column of today should be as faithful a representation of our ideas as was the ancients. Its use in porches, mantels, pergolas and other supports and ornaments entitle it to the most careful thought in designing it.

As instances of the class of work made by the American Column Company, we are able to show a pergola erected in their plant, where

t is seen from all the passing trains, and also an excellent example of long columns used in a Florida residence. Many other excellent examples of their work and methods of construction are shown in heir latest catalogue, which we believe is sent free to all interested, provided this magazine is mentioned.

CRESCENT WOOD WORKING MACHINERY.

Among the new features shown in the latest catalogue of the Crescent Machine Company, we find a 30x6 inch surfacer, guards for band saws, two more sizes swing saws, two more sizes jointers, and a post borer. A novel feature of the last is that it is arranged with a variable friction drive in place of the usual bevel gearing. This adapts the machine for running at high speed when using small bits and slow speed for larger bits.

A very complete line of power machines for all classes of woodworking is shown, and the catalogue should be before everyone interested in this line of manufacture. If you are not on the mailing list for this and future publications, advise the Crescent Machine Company, 10 Main street, Leetonia, Ohio, and they will keep you informed regarding their new products.

AN AUSTRALIAN SKYSCRAPER.

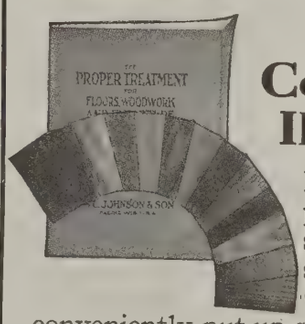
(From Consul General John P. Bray, Sydney.)

A contract has been signed in this city for the erection of the Culwulla Chambers, a block of business premises and offices, the cost to be about $590,000 and to be completed in two years.

The building will comprise 13 floors, with a roof garden and caretaker's quarters in addition. The ground floor is taken up with three spacious shops, with separate basement quarters. In addition to the usual elevator, provision has been made for an express elevator, which will take its first stop at the sixth floor. Other provisions are an electric freight elevator, 2,800 pounds capacity; a 5,000-gallon water reservoir for fire protection, which can be filled by an automatic electric pump in 3 minutes; a large vacuum cleaner in the basement, driven by an electric motor, and with tubes to all the floors; and letter-box tubes to each floor.

This 165-foot building will be the loftiest of its kind in the Commonwealth. The ground-floor piers are to be in polished trachyte, the first and second floors in freestone, and the remainder in red open-kiln bricks with freestone dressings. The internal joinery is to be Queensland maple, limed and waxed.

Write Us Now For Free Samples of Johnson's Artistic Wood Finishes



Johnson's Paste Wood Filler

is made in five shades for filling the grain of all wood, soft and hard. Manufactured from the best and most expensive silex, linseed oil and best Japan dryer and guaranteed to give satisfaction.

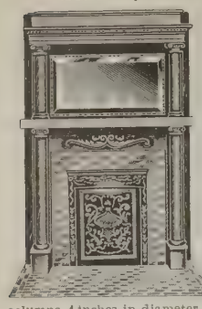
All wood which is to be finished natural should be given a coat of Johnson's Natural Paste Wood Filler No. 10 and a finish-wax, Under-Lac and Wax or Under-Lac and Varnish.

We recommend the use of our colored shades of Paste Wood Filler where a golden oak, dark oak and Antwerp finish is desired on hard woods, also for use over Johnson's Wood Dye where a filled grain effect is desired.

Ask your dealer for a free sample of any shade of Johnson's Paste Wood Filler

Johnson's Color Panels and Illustrated Book

Let us send you free a complete set of wood panels showing all shades of Johnson's Wood Dye on various woods. These panels are conveniently put up so that you can easily show them to prospective customers. By doing so we are sure you will procure many contracts at profitable prices for work to be finished with Johhson's Artistic Wood Finishes. The dye *always* matches the panels.



We will also send you a copy of our new book illustrated in many colors and containing color plates of the dye. This book gives full instructions for finishing and refinishing all wood—soft and hard. It is invaluable. Call upon your leading paint dealer for samples, wood panels and book. Or write us giving your dealer's name and we will send them to you from Racine. Ask for booklet Edition N. B.-8.

We Guarantee Safe Delivery.

Ceramic Mosaic Tile Floor, 16 Cents a Square Foot.

Also a wide variety of new and artistic designs in combinations of all colors up to 25 cents a square foot. Our Tile Book, reproducing patterns in colors, sent free on request.

Perfect Cleanliness Is Economy, Not Extravagance.

Modern hygiene demands Ceramic Mosaic Tile Floors for the bathroom, kitchen, pantry, laundry, vestibule and other places in the home, store, hospital, dairy, school, hotel and cafe.

Tile floors are aseptically clean, more enduring than marble and as easily kept clean as chinaware. The longer they are used the brighter they becomes.

We have put this former luxury within reach of the most modest purse. Our direct from factory selling plan and our improved method of preparing the tile for laying, so that anybody can lay a perfect tile floor without any previous experience, has cut the cost of these floors one-half.

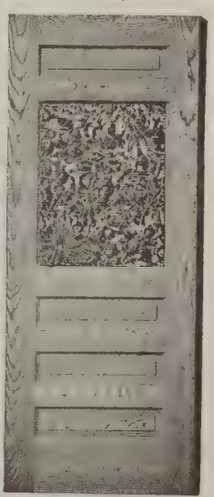
We furnish our Ceramic Mosaic Tile in the design illustrated for **only 16 cents a square foot.**

Our Tile Book shows similar savings in wall tile. Send for it.

Build an Oak Stairway at Half the Regular Retail Price of Yellow Pine.

$75.00 STAIRS, $22.80.

Choose your materials from our complete up to date assortment. Any workman of ordinary ability can build a perfect fitting and artistic staircase with our stairwork.



A bill of materials for a fifteen-step staircase in yellow pine of the design illustrated costs only $22.80 when ordered from our catalog. The same staircase bought from the average stair builder would cost you $75.00. Our bill of materials includes everything required—fifteen stair steps or treads, sixteen stair risers, one starting newel, two angle newels, twenty-six balusters, 18 lineal feet of rail, 34 feet of string board, 60 lineal feet of cove and fourteen stair brackets, all for $22.80.

If you will send for our Mill Work Catalog you will see that you have been losing money unless you have been building your own stairs.

Fine Teeth Need Fine Files

Filing a saw is one thing—putting a saw in trim to cut fast and true, without pinching or jumping, is another thing. Men who know that every kind of file isn't suited to every kind of saw, sharpen fine saws with

E. C. S.

KEEN KUTTER

Special Slim Taper Files

the slimmest files ever produced. Made from blanks of specially prepared tool steel that takes a hard and lasting temper. Milled by a new and improved method which cuts them absolutely even and uniform from tip to heel. This makes a fast cutting file.

Use an E. C. S. Special Slim Taper File and feel it "bite" the full length of the stroke—no lost labor—no slipping. These files—properly used—never change the shape of the saw teeth. Cut to the bottom without altering the bevel or lowering the point. Every mechanic's kit should hold an assortment of E. C. S. Keen Kutter Special Slim Taper Files.

TWO PRACTICAL BOOKS

PRACTICAL BRICKLAYING—SELF-TAUGHT. BY Fred T. Hodgson, F. A. I. C. 277 Pages, 300 Illustrations, 12 mo, Cloth Binding. Price.....$1.00

Bricklaying is becoming quite an art, and the "bricklayer" is becoming of as much importance today as he was in the 16th and 17th centuries. It is absolutely necessary now-a-days that, in order to take his proper place among the arts and crafts, he become familiar with all the minutiae of the trades. As much art can be displayed in brickwork as in any other of the trades, and it is up to the working bricklayer to get all the knowledge possible regarding his calling, so as to enable him to execute any kind of work relating to his trade. This book is designed to help him out in this matter, and discusses the various kinds of bond, ornamental brickwork, damp courses, quality of brickwork, forming of pilasters, quoins, skew arches, splay work, brick joints, chimneys, fireplaces, flues, brick-pavings, and many other classes of brickwork. The work contains 300 fine illustrations.

PRACTICAL STONEMASONRY—SELF TAUGHT. By Fred T. Hodgson, F. A. I. C. 300 Pages, 500 Illustrations, 12mo, Cloth Binding. Price.....$1.00

This book deals with stone cutting and mason's work, methods of building walls in rustic rubble, ashler square, uncoursed, random coursed, irregular corners, snecked and square rubble polygonal ragwork, and other styles of masonry and stone cutting are explained and illustrated. Finished stones, such as window sills, window heads, coping, arch stones, key stones, and similar dressings are described and illustrated. Stone arches and joints are described and illustrated, with ample instructions for working them.

The book contains hundreds of illustrations and diagrams, and is a complete cyclopedia of practical instructions in masonry and must prove of inestimable value to the operative mason.

Learn to Fill BIGGER SHOES!

Don't be satisfied with merely pushing a saw and driving nails Be a *master* of your craft. Learn to *plan* as well as to work—to use your *brain* with the *same skill* that you use your hands.

Learn to fill a *big-salaried* job—the kind of a job that hundreds of other men, with no more natural ability than you, are filling with ease and success.

HOW YOU CAN DO IT

You can *master every detail* of your line of work, *every branch* of building construction, *every angle* of architecture and carpentry—can do it in your spare moments and at almost no expense at all. You can have the knowledge and experience of over *four score experts* at your command, ready for instant use whenever you want it—can fit yourself to *fill any first class position above you that you desire*—simply by allowing us to place in your hands this great ten volume set *without your sending us one cent in advance.*

This Cyclopedia of Architecture, Carpentry and Building

is the most exhaustive, comprehensive and *practical* work on the building trades that has ever been published. It covers *every detail* of building construction from common carpenter work to reinforced concrete and steel; from masonry to heating and ventilation; from specifications and estimates to building laws and superintendence. It covers all the *practical* things that you *want* to know, all the things that you've *got* to know if you're going to be a success. It contains over 3,000 drawings, full page plates, diagrams, etc., has 4,670 pages, is bound in handsome half morocco and printed on special paper in large clear type—10 massive volumes—titles engraved in 23 karat gold. No *carpenter, contractor* or *building owner can afford to be without it a single day.*

Learn the Vitally Important, Practical Facts About

- Carpentry
- Building Materials
- Building Superintendence
- Reinforced Concrete

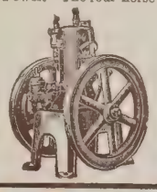
GASOLINE ENGINES

Equip Your Carpenter Shop with the Most Economical Power Known to Modern Science

The latest and most modern types ever placed before the buying public. Economical both in *price* and *consumption* of fuel. Will produce more *horse power* for *every gallon of gasoline used* than any other Engines in the market today. Brand new direct from factory.

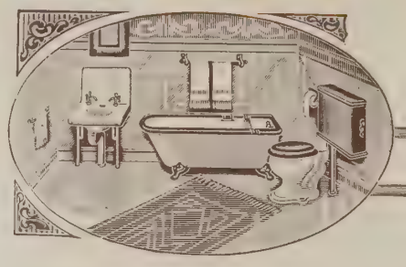
Price Wrecking Bargain 8 and 12 H. P. ENGINE **only $200 AND UP**



We are willing to have our Superior Heavy Duty Gasoline Engines compared with any on the market no matter what the price. Built with the greatest care and every mechanical detail is carefully provided for. Best Engine for all around work on the farm and in the factory. Most popular Engine we handle, powerful and reliable, made for heavy work and continuous service. The 8 horse power is large enough for the ordinary work on the farm, also for elevators, factories, etc. The 12 horse power we recommend for small threshers, silo fodder cutters, etc.

30 Days' Free Trial AT OUR EXPENSE | **OUR GUARANTEE PROTECTS YOU**

Our two horse power "Superior" Engine is designed to meet the demand for a low priced Engine to take the place of Wind Mills, Hand, Foot or small Tread Power. The four horse power is designed for general farm or machine shop work.



The simplicity of construction makes them the most serviceable, easy to operate and Practical Gasoline Engine ever produced. We can recommend them with the utmost confidence to our patrons to give entire satisfaction.

They are just as convenient as any Electric Motor or Windmill would be for pumping water, running cream separator, washing machine or other labor saving devices in the house. It does not require any more practice or experience to run or keep these engines in order than the Motor or Windmill.

Two Famous Silver Steel Saws

We want to call particular attention to the two Saws shown in the pictures below. Both blades are of SILVER STEEL—both are Taper Ground—both are genuine ATKINS SILVER STEEL SAWS—BUT the handles are constructed on entirely different principles.

No. 53. Genuine Perfection Handle

No. 51. Old Style Handle

"Pay Your Money and Take Your Choice"

ATKINS No. 53

The picture to the left shows ATKINS No. 53 SILVER STEEL SAW equipped with ATKINS Genuine Perfection Handle and illustrates plainly why this type of handle is easiest on the saw arm. While it may feel strange to the beginner—a few days use will demonstrate that the Perfection Handle is the most *scientifically* constructed and much easier on the saw arm than any other style.

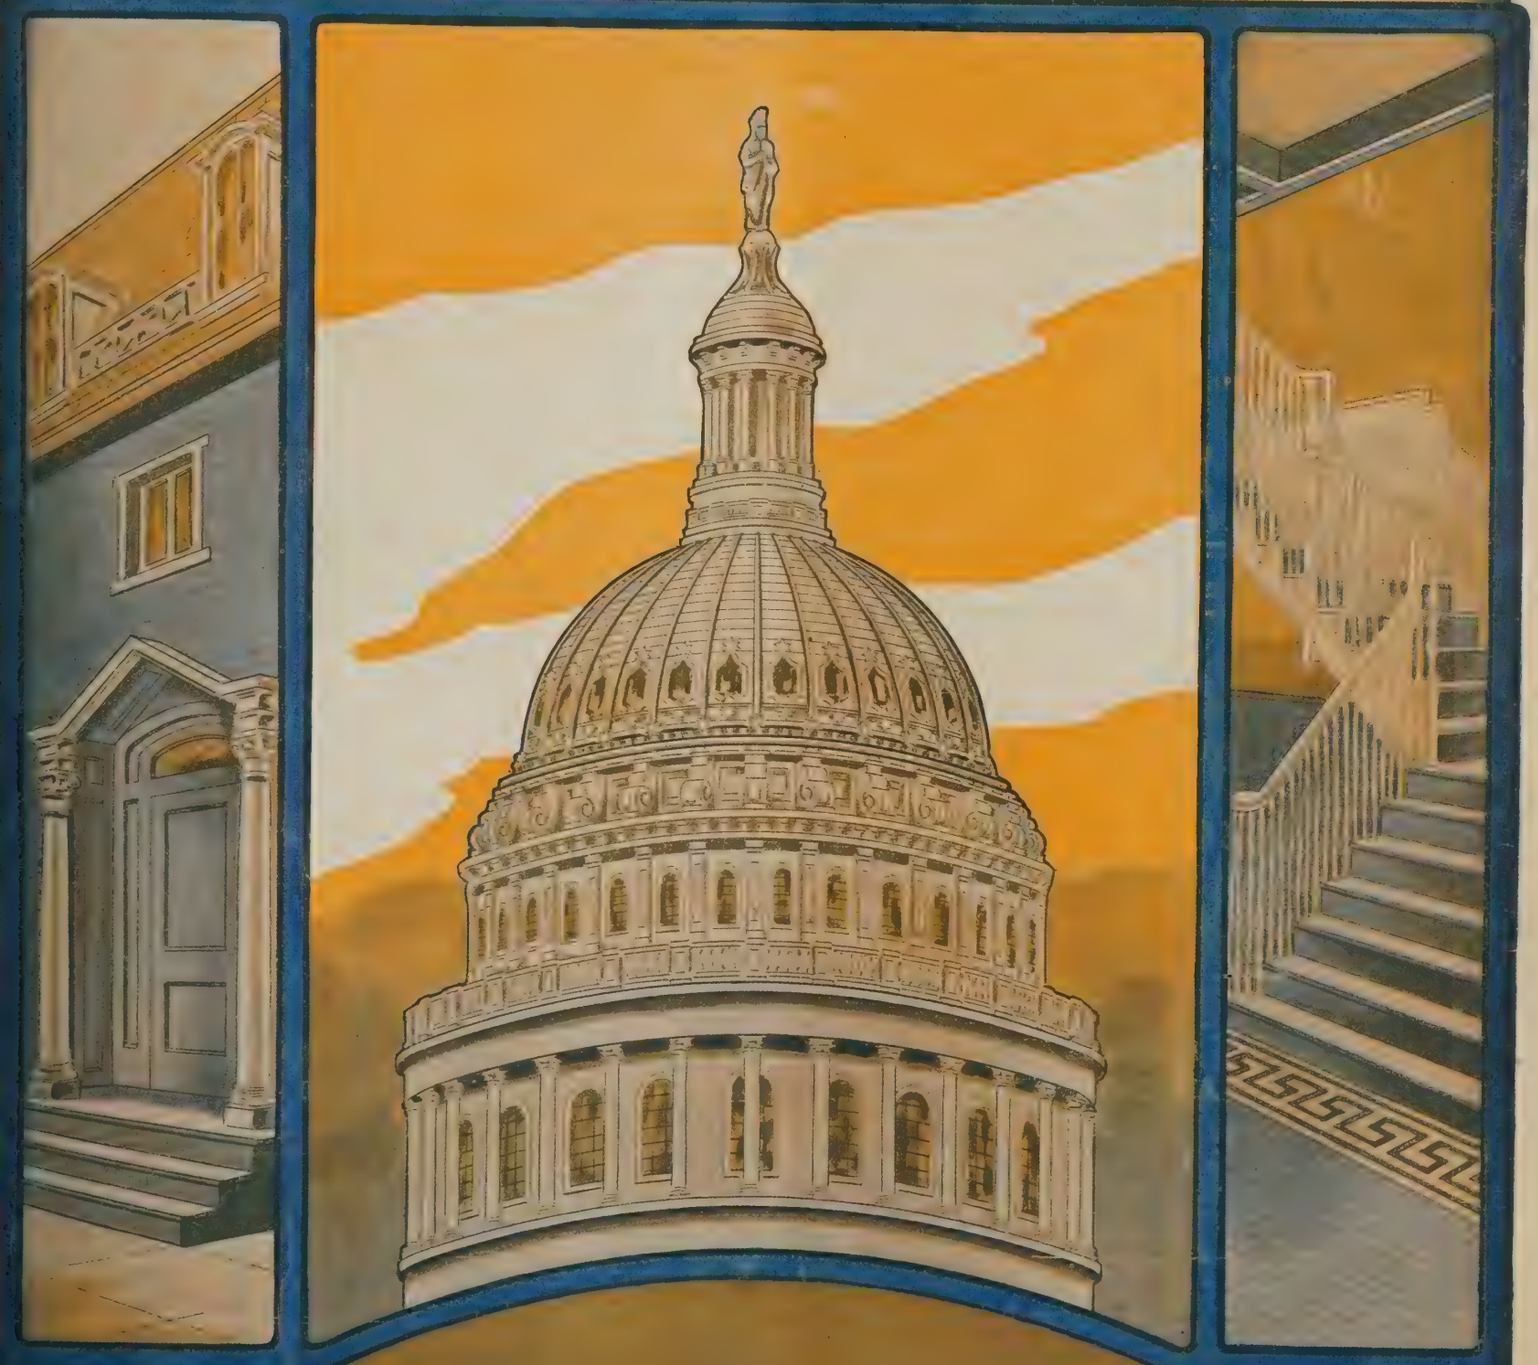
Note the line running through the saw arm straight through the blade to the cutting edge. See how every ounce of power is directed to the point of contact. Observe the wrist and saw arm, how easily and naturally the blade drops into its work without pressure.

ATKINS No. 51

If you are under the impression that all ATKINS SAWS are made with the Perfection Handle, we wish to particularly call your attention to the saw shown to the right. This handle is similar to the old straight across handle that you may have been using heretofore. Note the saw arm in this case and see that the pressure back of the saw arm is *not* directed on the cutting teeth, but rather to the back of the saw. Notice this wrist and see how it is necessary to push downward in order to secure proper contact. But even with this old style handle, the No. 51 is superior to any other, because the blade is made of genuine SILVER STEEL (our own exclusive formula) and is Taper Ground, which enables it to run free and easy, even in wet lumber, with but little set.

If you do not wish to try the Perfection Handle, then try the No. 51. Either of these saws or any of our other popular numbers may be purchased through your regular dealer, who should order for you from his wholesale house in case he does not carry them in stock. If he will not order for you, let us know and we will see that you are taken care of. Be sure to see that our name, E. C. ATKINS & COMPANY, and the words, "SILVER STEEL," are on the blade. None other are genuine.

OUR FREE OFFER



We are securing the names of high class mechanics who appreciate fine tools and if you will send us ten cents in stamps to pay postage, we will mail you one of our fine carpenter's nail aprons, Saw Sense Book, Time Book, and a great deal of useful information on the purchase and care of saws. Write today and learn "Who's Who" in the saw world.

Disston Saws, Files and Tools

For fifty-six years we have been making Disston Crucible Steel. It is made under the exclusive Disston process. The long life and cutting properties of Disston Saws are due to Disston Crucible Steel and the treatment it undergoes in our shops.

The Disston establishment is the ONLY ONE making steel for its full line of saws and tools—one reason why Disston Saws are uniformly durable and efficient.

Disston Saws are hardened and tempered by the exclusive Disston process.

It pays to buy Disston Saws and Tools. For any and every kind of work Disston Saws, Files and Tools are the most reliable.

We have been making saws for over seventy-one years.

BISHOPRIC WALL BOARD AND SHEATHING

ANY WEATHER is "Good Building Weather" when you use Bishopric Wall Board as a substitute for lath and plaster. It is cheaper and better and does away with all delays in building. It is nailed to studding dry, ready for immediate application of paper, paint, burlap, or any other kind of decoration.

FOR WALLS AND CEILINGS

Bishopric Wall Board Easily Applied

This substitute for lath and plaster is made of kiln-dried, dressed lath, imbedded in hot Asphalt Mastic, surfaced with sized cardboard and cut at the factory into 4x4 ft. sheets, which are easily and quickly nailed to studding, ready for immediate application of wall paper, paint, burlap, or other decoration.

It is applied dry, is guaranteed not to swell, shrink, warp, crack, flake or blister; is clean, sanitary, and odorless; is proof against moisture, cold, heat, and vermin; saves fuel in winter and keeps out summer heat; also deadens sound.

It is suitable for dwellings, factories, new partitions in old buildings, finishing attics, porches, laundries, cellar ceilings, garages, etc.

Applied Dry Winter or Summer

Shows Construction of Bishopric Wall Board.

PRICE WALL BOARD AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6.40 per crate, or $2.50 per 100 square feet, f. o. b. New Orleans, La., Cincinnati, or Alma, Mich. We ship from nearest point.

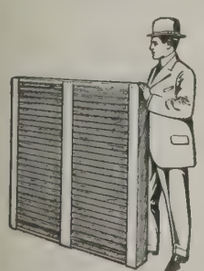
Cheaper Than Lumber. Saves 75% on Labor. Does away with Building Paper.

BISHOPRIC SHEATHING

Ideal Material for Cement Buildings or Stucco Exteriors. Proof against Dampness.

Bishopric Sheathing is made of same materials as Wall Board, but finish is not necessarily so fine, therefore costs less. It is of uniform thickness, insuring a perfectly even surface when applied.

Bishopric Sheathing is nailed to studs, with lath and asphalt side exposed. Over laths, weather boards are nailed or cement applied.



Shows construction of Bishopric Sheathing.

Arrow points to Asphalt Mastic into which laths are imbedded.

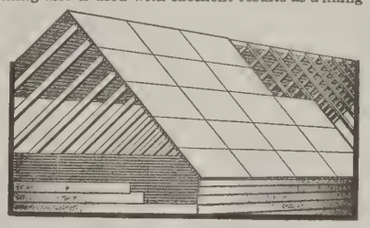
Bishopric Sheathing makes a more solid and substantial wall than lumber. There are no gaping joints; no widening cracks due to shrinkage; no knot holes.

The Asphalt Mastic in Bishopric Sheathing is a non-conductor, moisture cannot penetrate it. It is proof against vermin. The pests cannot bore through the tough, gummy Asphalt Mastic. In applying weather-boards over the laths, dead air space is left between the laths forming splendid insulation. Does away with the expense of building paper and cost of its application.

One Wagon load of Bishopric Sheathing covers an area from six to ten times as great as one load of lumber—a tremendous saving in hauling. Five thousand feet can be hauled in an ordinary wagon.

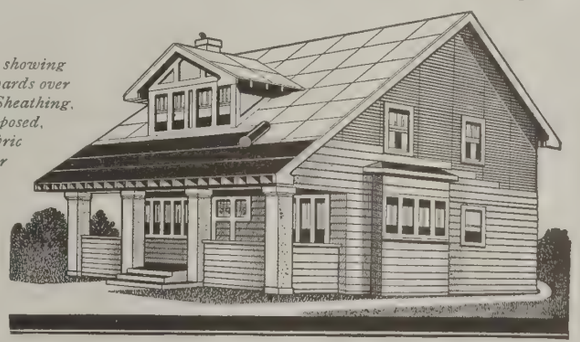
Wall Board and Sheathing are shipped in crates

The cost of applying Bishopric Sheathing is but $2.50 per 1000 feet—A SAVING OF ABOUT 75 PER CENT. Furthermore, 1,000 square feet of wood sheathing covers but 750 feet of surface, 20% less being due to tongue and groove. In Bishopric Sheathing 1,000 square feet covers 1,000 square feet of space



In applying ordinary lumber, heavier scaffolding, more tools and greater scaffold floor-space are required In applying Bishopric Sheathing, one man drives a few nails in each sheet; a common laborer or boy can finish the nailing.

Bishopric Sheathing insures comfort during the construction of the building. As soon as the building is closed in with Bishopric Sheathing, the men may work in comfort on the inside during bad weather, finishing the outside on suitable days. This insures continuous work, without loss of time, enabling the contractor to hold his men and complete the work in the least possible time.



Bishopric Sheathing is used with equally splendid results under flooring and as a substitute for roofing boards. Used under floors, it serves as a sound deadener and keeps out dampness; used under the shingles, it keeps out summer heat.

ITS MANY USES—Bishopric Sheathing also is used with excellent results as a lining for dairy barns, ranch houses, poultry houses, driving stables or any out-door building where protection from the elements, Summer or Winter is desired.

Bishopric Sheathing is the ideal material for cement exterior or stucco work. Cement firmly adheres to the laths and Asphalt Mastic and makes a solid, smooth exterior. For factory or residence this form of cement or stucco construction is the cheapest and best known.

Shows Bishopric Sheathing over rafters ready for Bishopric Roofing, also Weather-boards over Bishopric Sheathing.

Ideal home showing Weather-boards over Bishopric Sheathing, lath side exposed, also Bishopric Roofing over Bishopric Sheathing. (smooth side of sheathing exposed)

PRICE SHEATHING AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6, or $2.35 per square of 100 square feet, f. o. b. New Orleans, La., Cincinnati or Alma, Mich. We ship from nearest point.

Write for Descriptive Booklet and Samples of Bishopric Wall Board, Bishopric Sheathing and Bishopric Roofing—All will be sent free.

Don't Take Our Word For It—
Let Us Send You A Sample

TRY Utility Wall Board on just one job—Note how light in weight and how easily handled it is—Yet how stiff and substantial. Try it under the worst possible conditions and note how staunchly it stands up. No other wall board that was ever made is so moisture-proof and at the same time so readily adapted to any style of artistic decoration.

UTILITY WALL BOARD

is made of exceedingly tough, durable fibre. It is more satisfactory than any other substitute for lath and plaster. You can put wall paper over it with perfect safety. A wall or ceiling finished with Utility Board is permanent—there to stay as long as the building stands.

A New Beautifully illustrated book of interiors will give you some valuable ideas. Send for it at once. Also for the Free Sample

Utility Wall Board is sold through dealers in building supplies everywhere

THE HEPPES COMPANY

4502 Filmore Street **Chicago, Illinois**

INVESTIGATE Compo-Board

Best for Walls and Ceilings.

Better then than and plaster. More economical and durable. Can be put on in any weather and will stay up and look well as long as the building lasts.

Compo-board is made of strips of thoroughly dried lumber well glued. These strips are then covered with a specially prepared moisture proof paper, which is cemented under intense heat and pressure.

This makes a wall lining that will last indefinitely. Cannot crack or crumble off. Cannot chip off or mar by banging furniture into it. It is moisture and cold proof and fire resisting. Warm in winter and cool in hot weather.

Beside being a wall lining, Compo-Board has many other uses around the house and in the yard, in the office and factory. For remodelling the house or finishing off an extra room in the attic or basement, it is ideal. Summer cottages can be made as warm as the city home. Use it for partitions or back plastering.

Compo-Board can be had in strips four feet wide and one to 18 feet long, in any length in even feet.

SEND FOR SAMPLE AND BOOKLET

Fully describes Como-Board and its many uses and advantages, and the sample will show you what it is.

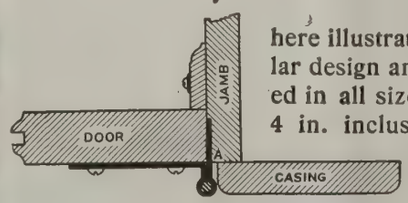
A Big Hit

Is the new tip with which "NATIONAL" Butts are now equipped, both Common and Ornamental.



The TIP is threaded and screws into the Butt in both the Japanned and Plated finishes.

It is also SLOTTED for A SCREW DRIVER, making it easy to remove the tip and affords ready access to the pin.

The slot also indicates instantly which is the bottom of the butt—a feature greatly appreciated by the carpenter.

These are exclusive "NATIONAL" features.

Style No. 450

here illustrated is a very popular design and can be furnished in all sizes from 1½ in. to 4 in. inclusive. These butts are highly polished, double plated and have beveled edges. They match escutcheon plates with beveled edges. Ask for "Catalog B" and give dealer's name.

TEN DAYS' FREE TRIAL

If you will take this ad to your hardware dealer and ask him to comply with this offer he will gladly do so; or, if he does not handle our squares and will not order one for you, write us, giving your banker's and grocer's names as reference. We will ship you one, express prepaid.

Guaranteed Accurate and to Remain So

The main feature of our new Take-Down Square is that it will always stay true. It is so constructed that the tongue is held down into beveled bearings by a spring, and these bearings are made so as to take up the constant wear which comes in taking square apart and putting it together, thereby producing constant accuracy. Rust-proof canvas case with each square.

	Polish	Ox. Copper	N. Plated on Copper
No. 3 Standard	$2.50	$2.75	$3.00
No. 100 Standard	2.75	3.00	3.25
No. 100R Framing	3.00	3.25	3.50
No. 100A Framing	3.25	3.50	3.75

Add ten cents to the price of the No. 100R and 100A if 1¾-inch tongue is desired.

Mr. Hardware Dealer—

Knowing that our new Take-Down Square is so constructed that it will remain true, we are willing to allow you the privilege of putting this square out on TEN days' trial. We will make good all squares returned to you, but all squares that come back to you must be returned to us through the jobber from whom you purchased these squares.

We are in no wise responsible for squares not returned or bad accounts herewith contracted.

NICHOLLS MFG. CO.

Ottumwa, Iowa

A roof is only as good as its waterproofing.

Knowing this, will you buy the covering for *your* roof on its "looks" alone, and not know what it is made of?

Genasco

the Trinidad-Lake-Asphalt Roofing

is waterproofed entirely with *natural* asphalt. In Trinidad Lake this asphalt has resisted blazing sun and terrific storms for hundreds of years. It has natural oils that give it lasting life in a roof despite the buffeting of rain, snow, sun, wind, heat, cold, and fire.

Man has tried to *make* lasting waterproofers—and always failed. Ordinary ready roofings show you what happens. They are made of mysterious "compositions" or coal tar; and they soon crack, break, leak, and go to pieces. Yet as for looks, they are mighty good imitations.

It pays to know about waterproofing when you buy roofing; it is a waste of money *not* to know.

The life and backbone of Genasco is Trinidad Lake Asphalt—the *natural* everlasting waterproofer—and that makes Genasco last. Genasco is made with mineral and smooth surfaces. Guaranteed, of course.

The Kant-leak Kleet waterproofs the seams of roofing thoroughly without the use of smeary unsightly cement, avoids nail-leaks, and gives the roof an attractive appearance.

Ask your dealer for Genasco Roofing, with Kant-leak Kleets packed in the roll. Write us for the Good Roof Guide Book and samples.

PHILADELPHIA

New York San Francisco Chicago

IN AND OUT SCREW DRIVER No. 41

THIS is the kind of tests to which Millers Falls tools are subjected. This reversible screw driver was tested with a mechanical device against a resistance equal to driving in a 1½-inch screw. One hundred thousand movements were made, and there was **not a sign of wear** at the end. How long do you think such a tool is likely to last you? Its sensible construction is responsible for this remarkable wear, for in designing it, every effort was made to avoid the defects which other reversible screw drivers were known to possess. In this reversible screw driver **one of the grooves is cut deeper than the other,** and in that simple, sensible manner the tool is made without any intersecting points of grooves at all; hence the remarkable wear it gives. The operation, too, is simple and easy, and if desired, the spiral can be locked instantly and the tool used as an ordinary screw driver at different lengths. This tool has proven one of the popular tools that we make. With each tool we supply three bits, two of them double end.

AN

"AMERICAN" SAW BENCH

MEANS MORE PROFIT ON THE JOB

The contractors making the most money today are those who are cutting out the little expenses on their jobs.

One of the greatest "Expense Cutters" ever put on the market is the "American" Portable Saw Bench—a machine for doing what has hitherto been done by costly hand labor, or else done at the mill, involving delay.

When you have an "American" Bench, you have, right on the job, the following:—

Rip Saw	Dado Machine	Boring Machine
Cut-off Saw		Rabbitting Machine
Gaining Machine	Mitre Saw	Jointer
Grooving Machine	Matcher	Moulder

They're all in the "American" Bench with self contained power, either gasoline or electric motor—ready at a moment's notice, always on the job.

Figure for yourself how much you could save on one contract by using "American" methods instead of hand labor.

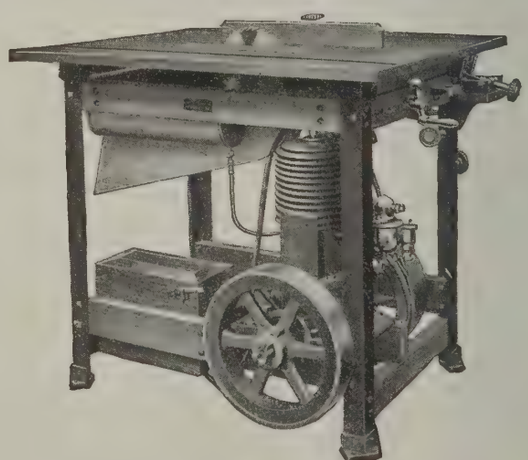
For this Portable Saw Rig Complete
9 Machines in One



Will rip 2″ and cross cut 3″ lumber
Write for descriptive folder

C. H. & E. Manufacturing Co., Inc.

319 Mineral St. Milwaukee, Wis.

Have You Investigated

The Grimm Woodworker

Type "A" with 4 H.P. Gasoline Engine. Weight equipped for work 350 lbs.

Nine Machines in One

8-inch Rip Saw	Boring Machine (3 bits)	4-inch Jointer
8-inch Cross Cut Saw	Moulder (8 prs. knives)	Jig Saw (3 blades)
6-inch Dado Head	10-inch Sander	Two Emery Wheels

Progressive building contractors are fast coming to realize the importance of substituting practical machines for hand labor. The **Grimm Woodworker,** furnished either with gasoline engine or electric motor and combining so many important attachments in one machine, is undoubtedly one of the greatest time, labor and material savers yet brought out.

Write for descriptive booklet and our attractive selling plans.

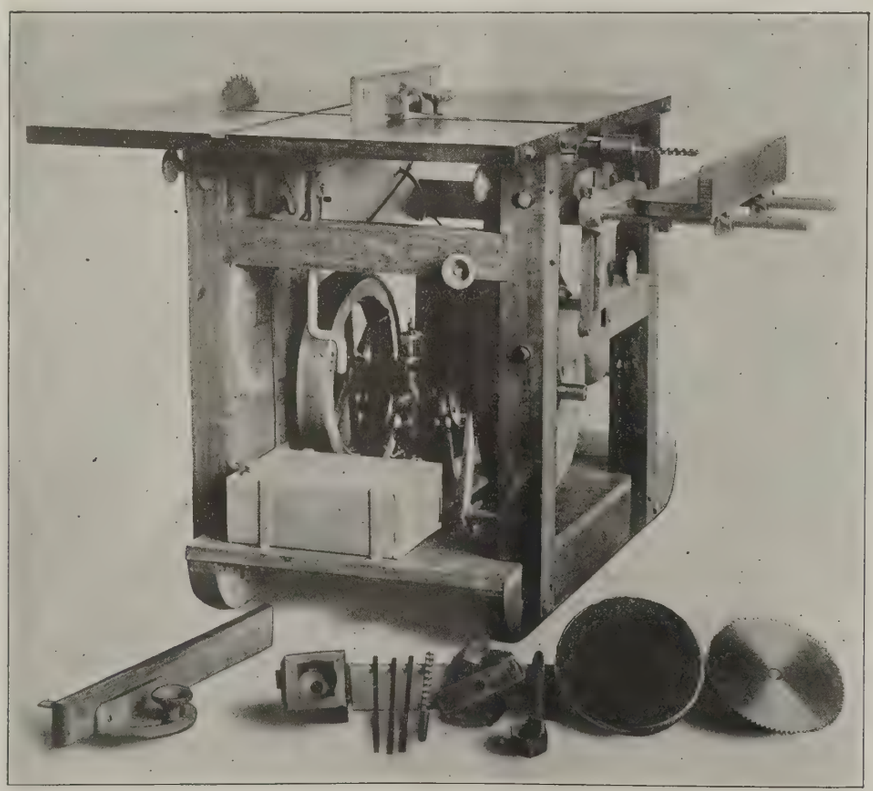
ANNOUNCEMENT



A year ago we commenced work on a portable saw rig, feeling sure, after talking with many contractors, both large and small, that this would fit the builders' work exactly—and overcome the drawbacks found in other portable rigs, such as lack of power, quality, attachments, service and ability to stand up under the most severe working conditions.

We have designed this superior rig with all the labor saving devices and none of the defects found in others. We are building them in the most modern and up-to-date factory, so well equipped in every way that it allows us to make an exceptionally low price on our rigs. We have so much confidence in them that we will sell you one on the following conditions:

IF NOT SATISFACTORY RETURN AT OUR EXPENSE

No charge for these attachments:

- 10-inch Ripsaw
- 10-inch Crosscut Saw
- 12-inch Jig Saw
- Boring Outfit
- 10-inch Sander
- 6-inch Dado Head
- 2½-inch Jointer Head
- Miter Device

This is the No.14 Famous Universal Woodworker

—there are more than six hundred FAMOUS Universal Woodworkers in use

There's no experimenting—no fear of taking chances. The FAMOUS Universal Woodworker has the endorsement of over six hundred carpenters, builders and contractors—*and is guaranteed for life.*

A Real Woodworker—*not a "make-shift"*

If you want more proof than our statements write to FAMOUS users—they'll give you all the proof you require. Their evidence is *indisputable.* The experience of six hundred men in your own line of business should aid you in making your choice.

Every one of these six hundred users has convinced himself that the FAMOUS is a *real* woodworker—not a makeshift piece of machinery, made to sell. Every FAMOUS user is thoroughly satisfied—every one is getting the services of sixteen machines—every one is getting cheaper and better "millwork service" than ever before.

Write today for literature and copies of letters written us by FAMOUS users.

"The latest invention, and without comparison the most practical, up-to-date woodworker made."

Buffalo Crain Combination Woodworker

Note the ample size and capacity of the parts which perform the four vital operations in your shop: **1. Lathe**—40″ between centers; **2. Band Saw**—taking 12″ under the guide; **3. Saw Mandrel**—taking saw sup to 12″ dia.; **4. Planer Head**—taking 5″ or 10″ bits. The convenient location, strength, simplicity and easy adjustment of these vital parts, are of the greatest advantage. Drilling, boring, sizing, jointing, moulding work, tenoning and, in short, practically every operation of daily occurrence in a woodworking shop, can be performed on it **without extra attachments.** As an investment, it is a true gold mine. **Three men can work at it at one time.** Lowest power cost. Ask for Booklet 1785.

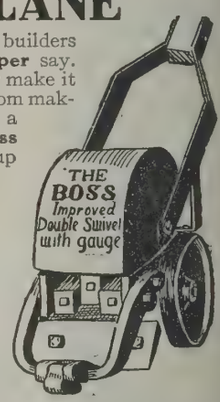
1001 Flatiron Bldg. NEW YORK.

Acme Floor Surfacing, Laying & Finishing Co. Not Inc.



IT'S A SCRAPER BUT IT WORKS LIKE A PLANE

That is what the many satisfied contractors and builders who are using the **Boss Improved Floor Scraper** say.

The **gauge** on the front and wheels at the rear make it like a plane. This gauge, which keeps the knife from making a depression in the floor, gives the knife a double support. It can be set for **any thickness of shaving,** or **instantly removed** for working up into corners.

Deep Cutting is prevented by the pear shaped wheel in front, which lets the knife down gradually to make the cut.

Poor work is **impossible** as with the simple but positive adjustment of this gauge and wheel attachment the knife leaves no mark. The standing attachment cleans the wheel and takes off the rosin when working hard pine.

Price very low. Write for descriptive Circular "N"

GEORGE J. KEPPLINGER, - Dwight, Illinois

When You Buy a Floor Surfacing Machine
BUY A GOOD ONE—IT PAYS!

The Triple "A" Spring-Driven Floor Smoother combines the advantages of the hand machine and the power machine. No more expense than the former, yet has the capacity and ease of operation of the latter.

No wasted energy pulling a dead weight.

About half of all the Triple "A"s sold have been bought by owners of dead weight machines. What's the answer?

"Get the best first and save extra expense."

The Triple "A" to be appreciated needs only to be seen in operation.

For advertising purposes we will give a special discount on the first machine sold in each town.

The WEBER DOUBLE ACTING Floor Scraper

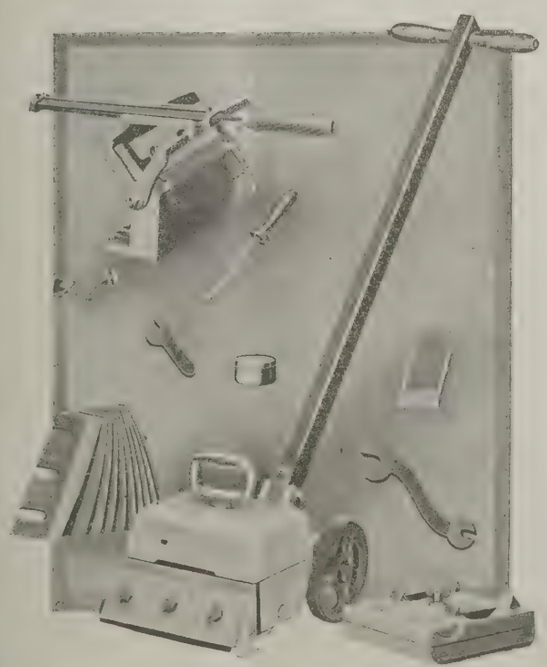
The WEBER knives adjust to any desired slant for perfect work on all conditions of flooring. The WEBER is guaranteed not to chatter nor leave waves. The knife is held to its work—not by a dead weight—but by a flexible joint—similarly to action of human hand. The WEBER scrapes forward and backward. It has two knives, either of which can be brought into instant action. This rests you—saves your time—and enables you to scrape the centers of very small rooms. I guarantee perfect work in either direction. The saving in time and money in a year is a big item. The WEBER scrapes right up to the wall. By adjusting the handle to the right or left (see dotted lines), the extreme edge of the knife comes into direct draft with it. You can scrape right into the very angle of the floor without side draft, or marring the baseboard.

Try It Five Days FREE

Send for this scraper. Take it right out onto the job. Put it up against any other scraper made—on any kind of flooring. If its work isn't better in every way, return it.

Write Me Now

I also sell Wax Polishers, Saw Filing Vises, Cabinet Scrapers, Double-Folding Scaffold Brackets, etc.



Weber No. 1

This is my latest model. Note the handle adjustment, two knives, excellent balance, and workmanlike finish thruout. Made to save time and it *does* it.

John F. Weber, Pres., WEBER MFG. CO.
661 71st Avenue - - - - WEST ALLIS, WIS.

It is Yours for the Asking

To Try It for One Week

The Acme Floor Scraping Outfit

No "If's" or "Ands" about my offer. It is a straight business proposition and one that I have adopted to make sales. It is impossible for me to send a representative to every contractor interested in a floor scraper, so instead, I send the Acme Floor Scraping Outfit to represent itself.

I allow you to work with the machine for one week and if at the end of that time you are not satisfied with the results and do not consider the Acme Floor Scraping Outfit the best equipment on the market, simply pack it up and ship it back to me at my expense.

Does this sound like an offer that is worthy of your consideration?

Further particulars and catalog on request.

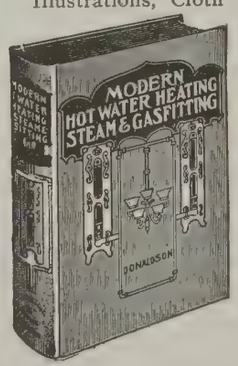
USEFUL BOOKS FOR CONTRACTORS

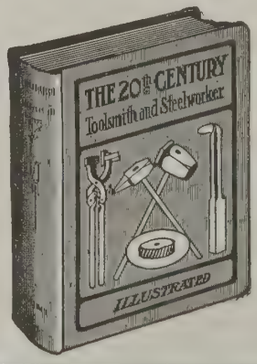
PRACTICAL UP-TO-DATE PLUMBING. By George B. Clow. 310 Pages, Over 250 Illustrations, Large 12mo, Cloth. Price.....$1.50



A practical, up-to-date work on Sanitary Plumbing, comprising useful information on the wiping and soldering of lead pipe joints and the installation of hot and cold water and drainage systems into modern residences. Including the gravity tank supply and cylinder and tank system of water heating and the pressure cylinder system of water heating. Connections for bath tub. Connections for water closet. Connections for laundry tubs. Connections for wash-bowl or lavatory. A modern bath room. Bath tubs. Lavatories. Closets. Urinals. Laundry tubs. Shower bath. Toilet room in office buildings. Sinks, Faucets. Bibb-cocks. Soil-pipe fittings. Drainage fittings. Plumber's tool kit, etc., etc. The composition and properties of solder and how to make it, are carefully treated and a chapter is devoted to useful information. There are given a large number of valuable tables giving the pressure at different elevations, capacity of pipes, etc. The work also contains over fifty carefully prepared drawings, giving complete piping connections for home, tenement and office buildings.

MODERN ESTIMATOR AND CONTRACTOR'S GUIDE. FOR PRICING ALL BUILDERS' WORK—WITH MANY TABLES, RULES AND USEFUL MEMORANDA. By Fred T. Hodgson, F. A. I. C. 318 Pages, 100 Illustrations, 12mo, Cloth. Price.....$1.50

One of the most desirable books for the general builder to have, is a good and reliable work on estimating; and we are certain the book we are now offering, if the large number of favorable testimonials and press notices we have received is any indication, is one of the best, and most reliable books on the subject that has ever been published on this continent—or any other for that matter. We have no hesitation whatever in recommending this book to our patrons who want a good work on estimating. The work gives a lengthy and clear explanation of the several methods employed in estimating, among which may be mentioned, "Estimating by comparison," "Estimating by the cubic foot," "Estimating by quantities," "Estimating in detail," and several other systems.



HOT WATER HEATING, STEAM AND GAS FITTING. By Wm. Donaldson. Large 12mo, 250 Pages, Over 100 Illustrations, Cloth Binding. Price.....$1.50

A modern treatise on Hot Water, Steam and furnace Heating and Steam and Gas Fitting, which is intended for the use and information of the owners of buildings and the mechanics who install the heating plants in them. It gives full and concise information with regard to steam boilers and water heaters and furnaces, pipe systems for steam and hot water-plants, radiation, radiator valves and connections, systems of radiation, heating surfaces, pipe and pipe fittings, damper regulators, fitters' tools, heating surface of pipes, installing a heating plant and specifications. Plans and elevations of steam and hot water heating plants are shown and all other subjects in the book are fully illustrated.

The closing chapter, devoted to useful kinks, contains information on a variety of subjects which will be found of interest and value to the workman, as will also the many useful tables given at the end of the volume.

THE 20TH CENTURY TOOLSMITH AND STEEL-WORKER. By H. Holford. 240 Pages, 120 Illustrations, 12mo, Cloth Binding. Price.....$1.50

This book is written in the interests of all mechanics connected with the working and manufacture of steel into tools, and gives all the secrets and obstacles to be overcome towards making steelwork or toolmaking a success. It will be invaluable to the young mechanic and place him years in advance of his fellow workman, by the reading and a little reflection of its contents.

It is not comprised of quack theories or foolish ideas, and is not written by a college student, who knows nothing except what he has been told or gathered up from papers and periodicals. But is written by a thorough expert mechanic who has spent the best part of his life over the anvil with the hammer and tongs.

DO NOT BE DECEIVED

As to the Patent Situation on Asbestos Shingles

Some of our competitors have been misrepresenting a decision and injunction obtained from the United States Courts alleged to prevent us from selling Asbestos Shingles.

READ THE LATEST INJUNCTION ISSUED BY THE COURT

THE PRESIDENT OF THE UNITED STATES to
ASBESTOS SHINGLE, SLATE & SHEATHING COMPANY,
GREETING:

WHEREAS, it has been represented to us in our Circuit Court of the United States for the Southern District of New York that you, the said Asbestos Shingle, Slate & Sheathing Company, have misrepresented to the public the force and effect of a certain interlocutory decree entered by said court on the 16th day of February, 1911, in a certain suit brought by said Asbestos Shingle, Slate & Sheathing Company, and Ludwig Hatschek, against the H. W. Johns-Manville Company, and also the force and effect of our writ of injunction issued thereunder on the 18th day of February, 1911.

NOW, THEREFORE, we do strictly command and enjoin you, the said ASBESTOS SHINGLE, SLATE & SHEATHING COMPANY, from in any way advertising in words or in substance that this court has held that any cement shingles hitherto made and sold by the defendant H. W. Johns-Manville Company infringe on any of the claims of the patent in said suit, or from issuing any circulars or in any other way publishing abroad or saying, or writing, that this court has held that no cement shingles can be purchased except from the complainant, or that all the claims of the complainant were upheld by the interlocutory decree herein, or in any other way misstating the effect of the said decree, or of publishing the whole or any part thereof or the substance of the same, so that it shall mislead any reader as to its meaning or effect, and

We do further strictly command and enjoin you, the said ASBESTOS SHINGLE, SLATE & SHEATHING COMPANY, that whenever you shall advertise the interlocutory decree of this court entered in said suit, or any part thereof, or the substance of the same, in connection with the words "cement shingles," or "asbestos shingles" or the like, that in every such case the said advertisement or circular or other means of publication shall make equally salient to the eye the fact in substance that the said decree of this court forbade the making, vending or using of cement or asbestos shingles or the like, **made upon a paper-making machine,** and that said advertisement shall nowhere contain any statement that the decree of this court forbade the making, vending or using of any cement or asbestos shingles unless such statement be accompanied as aforesaid with the statement in substance that the said shingles so forbidden are those made upon a paper-making machine.

WITNESS THE HONORABLE EDWARD D. WHITE, Chief Justice of the Supreme Court of the United States, at the City of New York, on the first day of June, 1911, and in the hundred and thirty-fifth year of the Independence of the United States.

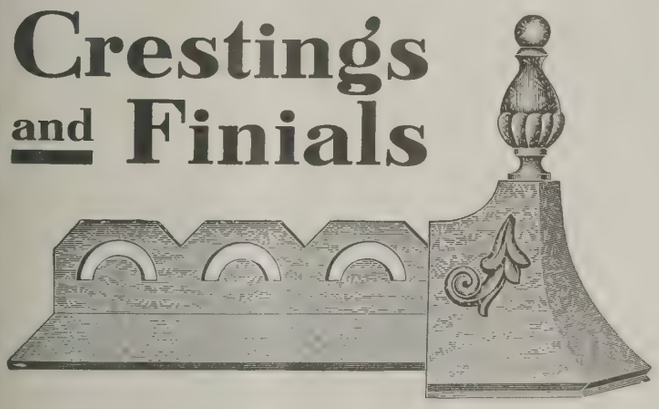
JOHN A. SHIELDS, Clerk of the Circuit Court.

We have been and are selling shingles which do not infringe our competitors' patents, because they are made by a new and better process, covered by letters patent which we control.

J-M Transite Asbestos Shingles
are not made like paper on a paper-making machine

The facts are that if you want Asbestos Shingles **made on a paper-making machine,** you must secure them elsewhere. We do not make that kind. But if you want the latest and best form of Asbestos Shingles made by the most improved methods, you can get them from us and no one can stop your using them.

Advise Us and We Will Protect You



We shall appreciate any information you can send as to any violation by our competitors of the above injunction.

You Can Pay for the Mixer on a Single Job by the Greater Economy of Operation

It is not alone the saving of one-third in first cost, one-half in power, one man to operate the hoist and two-thirds the delays and repairs, but the greater portability enabling it to always be kept at the most convenient position on the job for rapid work, that are the distinguishing features of the

Eclipse Concrete Mixer

And we offer our patrons not only greater economy of operation, but unequalled service in shipment. We carry 100 Eclipse Mixers in stock at our factory, stores, warehouses and branch houses for immediate shipment.

It is pre-eminently the mixer for the contractor because it saves money in nearly every possible use.

Our new 1911 catalog No. 32 is just off the press and gives full information how to handle the Eclipse to obtain best results. Write for it. Our testimonial booklet explains how other contractors are making money by using the Eclipse Mixer.

You can buy the small size Eclipse Batch Mixer Complete with Power at a lower price than a Continuous Mixer.

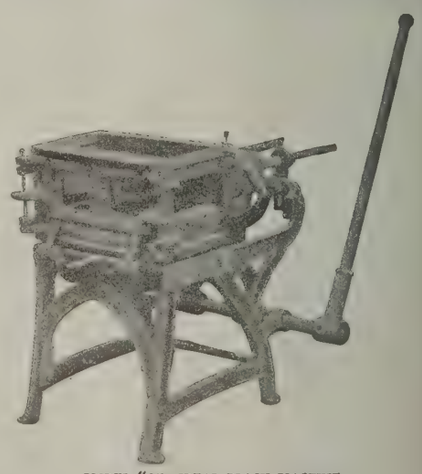
It Pays to Look Ahead



The man who looks ahead is the man who gets ahead.

It has ever been so, since the day Noah looked ahead and built his Ark.

The man who looks ahead and sees a large vision of the future—is the man whose future will be big in accomplishment.

If you aim for a big success, you must have a big vision.

Today hundreds of men have been ***big*** enough to see why the **Ideal Block Machine**—the one pictured on this page—is a money-maker. These men are reaping the reward of their "vision." Right now, to you—this **Ideal Block Machine** opens the road to wealth—gives you the key to the treasure house of concrete block making.

MODEL "A"—IDEAL BLOCK MACHINE

Why? Because with this single machine you can make the greatest variety, the best and most salable concrete blocks.

Because, as the sure growth of your business demands greater output, you can meet the demand, at the same time decreasing your cost and increasing your profits, by the addition of certain automatic machines and attachments, all of which can be used with your Ideal Block Machine as a basis.

Mail Coupon for Our Catalog Mail the coupon for Catalog No. 12 and learn full particulars of this modern business-builder—the **Ideal Block Machine.** If interested in other equipment besides Block Machines, *please check off* same on coupon. Learn why the **Ideal** line is called **"The Most Profitable Machinery in the Most Profitable Business."**

"The Largest Line of Concrete Machinery in the World"

Northwestern Contractors' Power Batch Mixer

This machine combines all of the features which every contractor or concrete worker desires in a mixer. It has such a low intake that the material can be shoveled in from the ground or a small platform built and the material dumped right into the mixer with wheelbarrows. It has a high discharge and will empty into a wheelbarrow or into the forms. It is light and portable and can be readily moved from place to place. It has automatic watering tank and can be adjusted to discharge any given amount of water each batch. It will hold a full sack of cement with practically any mixture. It can be equipped with a power, stationary loader or low platform. We guarantee that this mixer will cost you $100 to $200 less than any standard mixing machine of equal capacity on the market.

Don't Fail to Send for Our Big Catalog

We manufacture everything in the concrete machinery line, including mixers of every style, size and description and we can furnish everything that you might need in the concrete line. Regardless of whether you are in the market or not you should have a copy of this catalog. Please state what you are interested in as we issue four (4) special catalogs. We are the largest manufacturers in the world and prepared to serve you with machines extremely low in price, simple in design and speedy in operation.

How Much Salary Are You Worth?

What can you do that any one of a million others could not do just as well? How much result-increasing or expense-decreasing knowledge can you bring to bear in your work? Have you any special ability? Is there any reason why an employer should single you out for more than average pay? Or are you just an average workman?

Look the facts in the face. "What can you do?" "How well can you do it?" "How much are you worth from your neck up?"—that's the line of talk Old Industry hands out to the candidate for prosperity. Are you ready with the answers?

If you knew the ins and outs of some trade or profession—if you knew the **why** as well as the **how**—you wouldn't have to ask for more pay. You'd just naturally get it. The **Help Wanted** columns of trade papers teem with appeals for trained men. Draftsmen are wanted; foremen are wanted; superintendents are wanted; machine designers are wanted; chemists are wanted; advertising men are wanted; electrical, civil, mechanical, and mining engineers are wanted; architects are wanted. Your salary will always be governed by the kind of work you are prepared to do. How much salary are you worth?

The business of the I. C. S. is to raise salaries. And the more than 400 voluntary letters sent to Scranton every month to tell of positions bettered and salaries increased through study of I. C. S. Courses prove how well the big institution is doing its work. No matter where you live, how insufficient your education, nor how small your means, the I. C. S. offer you a sure way to a better job. They have been increasing salaries for 20 years. They are doing it now. They are not going to stop.

It will cost you nothing but postage to find out all about the I. C. S. plan for making you worth more salary. Mark and mail the coupon. Doing it will place you under no obligation. Don't wait till tomorrow. Don't take chances on "put-it-offism."

MARK AND MAIL THE COUPON NOW

International Correspondence Schools
Box 1332, SCRANTON, PA.

Please explain, without further obligation on my part, how I can qualify for a higher salary and advancement to the position, trade, or profession before which I have marked X.

Mighty few Carpenters try to get along without

Sebco Expansion Bolts

As a matter of fact practically all the live mechanics of the country are users of Sebco Expansion Bolts. Every Carpenter who has work to do that entails the fastening of fixtures to walls where ordinary screws will not hold, should learn to use the Sebco Expansion Bolts for heavier work and the Sebco Screw Anchors for lighter work. These Expansion Shields are a patented device made of composition metal with two shields grooved inside and teethed outside. When the screw is inserted in the shield it expands with each turn, making it impossible to pull out. You should let us send you some working samples and our catalog—we illustrate and describe many uses for our Expansion Shields and other products that will interest you and show you a way to do better work at no additional cost for labor or material. Tell us the work you are doing; we will offer suggestions and send you working samples.

SECOND FLOOR PLAN

THE NATIONAL BUILDER

Vol. 52 CHICAGO, AUGUST, 1911 No. 8

THE WEBB HOUSE, built near Chicago, Ill.

NATIONAL BUILDER DESIGN No. 344

Perry and Thomas, Architects, Chicago

For Floor Plans, Elevations and Details, See Supplement Sheet of this number. Estimated Cost, $3,390.74

IN the house shown on this page, and in detail on the supplement sheet, we have the ideal home for a small family. Complete on the first floor, it takes the form of a five-room bungalow, while at slight additional expense the second floor may be finished into two good rooms. Possibly the only use of the second floor would be for storage or a rainy day playroom for the children, but in time it is probable that at least one room would be finished off for the use of the occasional guest.

ESTIMATE OF THE WEBB HOUSE

The estimated cubic feet within the walls of this building from bottom of cellar is 30,800, which makes the average cost very nearly 11 cents per cubic foot.

EDITORIAL NOTES AND COMMENTS

"Waste not, want not."

This motto is as correct philosophy today as it was when first coined.

* * *

How much better off would we of the United States today be if our forefathers of a hundred years ago had kept this motto in letter and spirit, with regard to our forest and other resources. The magnificent timber limits that suffered from the indiscriminate use of the axe, and the destructive ravages by fire and flood, that could have been avoided in a large measure, if proper steps had been taken to prevent or minimize the terrible waste, would have left things in a much better condition than they are now!

* * *

Many governments, besides our own, are taking strong measures to prevent these wholesale devastations, and stringent laws are being enacted in every civilized country to prevent fires and floods, so far as human foresight can reach. It is every man's duty to aid in the prevention of useless waste, wherever it is possible for him to do so, and every man should be imbued with this spirit, particularly if he is engaged in some occupation requiring his presence in or near a densely wooded district. The free and careless use of matches, and the lack of care by smokers, are accountable for the loss of millions of dollars worth of valuable timber, and hundreds of precious lives.

* * *

There are other sources of waste as well as those caused by fire or flood, that are in a measure unnecessary, and in many cases avoidable, and that are almost criminal. We refer to the tearing down and partial destruction of good healthy buildings in order to give place to larger and so-called more modern structures; a condition much to be deplored. Why should a good building, having no serious faults, either in construction or style, be eternally destroyed in order to make room for a more pretentious structure? We have in mind, at this writing, several buildings in Chicago, New York, and other cities, whose erection cost well up towards a million dollars each, being taken down in order to make room for larger and more modern structures whose cost each will, in most cases, be more than double—and in one instance we know of treble—the cost of the original buildings. How much better it would be to leave the older buildings standing, and build the new ones on sites near by, We are aware of all the objections that can be brought against a new site, but they do not suffice to convince those who will examine this question thoroughly. In the first place the municipality is a loser, inasmuch as one million is cut off the tax roll, and a two million figure is placed therein; but were the old building left with its one million assessed value, and the two million new building added, the municipality would assess three millions instead of one.

* * *

This, however, is not all. The consequent improvements growing out of the new erection would so increase the assessed value of the surrounding property that the body corporate would find itself very much enriched, and the disturbance of business during building operations would be avoided. The further extension of corporate limits, or the filling up of vacant spaces, would naturally follow, thus benefiting a whole neighborhood, without disturbing the even tenor of an established locality. If a structure is condemned as dangerous to life or property, or for some unsanitary reasons, by those in authority, it is proper to have it demolished, otherwise it seems to us a crime against society and economic law, to tear down a good building to make room for a larger or more modern one. We hear some one say, "There is no waste in tearing down a building these days." Well, let us see how this assertion pans out. Wreckers inform us that in taking down brick buildings, that if the workman can care for the bricks taken from the wall, so that 75 per cent may be used in other work after being cleaned and properly stacked, it will be a good showing, 50 per cent being much nearer the average. In stone buildings, much of the value of the old walls when removed, will depend on the character and style of the building, but rarely or ever can more than 80 per cent of the old material be used over. All lathing, plastering, painting, decorating, plumbing, roofing and a host of other things on the older buildings will, of course, be rendered useless—and lost—and generally the foundation walls can not be used again. The same may be said of cement work—unless in blocks—all of which makes a tremendous waste which is lost to the owner, the municipality, and the nation.

* * *

The waste, however, that will be worst of all, and that will affect the nation most, is the destruction of the woodwork that follows the dismantling of every building. It is quite true that most of the doors, sashes, frames and some fittings, can be carefully removed so that they may be used again in some situations, but the great bulk of them are unfit to place in where good stylish work is required. Door and window trim can sometimes be used to advantage, but not often where good work is required; under any circumstances, there will be much cutting, and chipping, and loss. Base, wainscot, mouldings, and such other work, may be sometimes used but is subject to a loss of some 50 per cent, unless the greatest of care and much time are expended upon them when taken down. Roof coverings, except rafters, or other timbers, are mostly useless and unfit for any purpose. Heavy timbers, beams, joists, trusses, posts, studs, girders or other timber work, loses at least 50 per cent of its quantity when cut and wrought for other purposes. Floors of all kinds in wood are almost worthless after taking up—not 25 per cent of it being available for future use. As a rule, stairs, handrailings and balusters may be made to answer in some situations, at a loss of from 20 to 25 per cent of material. Here then is a showing which exhibits complete loss of good material, of at least half the total. This is an extravagant waste, that is as unreasonable as it is uncalled for. People preaching conservation of our natural products should devise some scheme to prevent this useless waste and destruction of wood product now in actual use; and save to the country many thousands of dollars worth of timber that is now annually lost.

This country is not hemmed in by limits—it is a land of great areas and extended distances, and our towns and cities are not confined within moats and stone walls. There are plenty of vacant lots within corporate limits, and millions of them beyond, yet adjacent, that are available for building purposes, and it would seem to be more sensible to give our structures more base, and less altitude. If a system of building broader, with less height, was adopted, the habit of tearing down to make room for other buildings would soon cease and the country would be the better for it, and a great deal of waste in material and labor would be prevented.

* * *

We are gradually overhauling our liability laws and introducing semi-compulsory compensation for industrial injuries and fatalities. But the process is slow—painfully slow, owing to conflicts of authority, state rights and constitutional snags. Secretary Nagel is right in saying, as he did recently, at a convention of the National Electric Light Association, "That we must rely for years to come on the best motive power in any community—private initiative and enlightened interest."

The association just named, following largely the admirable example of the International Harvester Company, had announced the establishment for its 600,000 employes of a voluntary system of insurance against accidents, of old age pensions, and death benefits, as well as of savings and investments.

* * *

Private liability and compensation systems are always "compensational." They are the product of good will, and they in turn deepen and strengthen good will. Broad-minded, progressive employers know that such systems make for efficiency, peace and stability. Why wait for legislation and the litigation that legislation entails?

We are behind Europe in our industrial insurance and compensation arrangements. Manufacturers frequently oppose this or that liability or compensation bill as unfair, but they realize that the country is open to reproach and indorse the principle of proper compensation for accidents and injuries. Why not embody fair and sound ideas of compensation and liability in voluntary schemes? Why not blaze the way for legislators?

CALIFORNIA'S MODERN MISSION BUILDINGS

By HORACE F. STOLL

WINTER HOME OF A. C. BURRAGE AT REDLANDS, CAL.

It is wonderful what a fascination the crumbling walls, the tottering towers and the roofless arches of the California missions have for the sightseer and visitor.

Realizing this, the directors of the Panama-California Exposition, which is to be held at San Diego simultaneously with the great international fair at San Francisco in 1915, have decided to use as their main buildings careful reproductions of the missions reared by the padres. To carry out the illusion, the attaches will be dressed in Spanish costumes and although no attempt will be made to duplicate the interiors, since they are intended for exhibition purposes, they will doubtless prove a delight to visitors from all over the world. For instead of traveling two-thirds of the length of the state to steep themselves in mission lore and atmosphere, they will be able to saunter through Balboa Park and in a short time get a good idea of the general exterior appearance of all the notable missions, such as San Luis Rey, which is without doubt California's most poetically environed landmark; San Juan Capistrano, of most tragic memory; San Gabriel, the most imposing; San Diego, the oldest; Santa Barbara, the most perfectly preserved; and Mission Dolores, the cradle of Christianity and civilization in San Francisco.

From the first, the shrewd hotel men of Southern California have realized that the commercial value of the mission is nearly as great as their architectural worth, since they advertise the state as nothing else can. To satisfy the demand of tourists for something "different" from the conventional, they erected picturesque mission hotels. The railroads promptly sprinkled the southland with low, rambling mission depots and in their wake appeared mission country club houses, libraries, theaters, school houses, city residences and modest little homes. The result has been so pleasing and pronounced that California has come to be known as the only state in the Union that can boast of having evolved a distinctive type of architecture.

Of course, one encounters many "mission" buildings that are mission in name only. And as one architect, who has made this type of construction a specialty, remarks: "Sixteen inch walls will not give the effect of six-foot ones," nor do "milled woodwork, machine iron work and stock hardware surprise and charm as do their ancient hand wrought materials."

Of the thousands of mission buildings I have studied during my journey through California, I think the one most suggestive of the romances of the early history of the state is the New Glenwood Hotel, at Redlands, colloquially known as the Mission Inn. Here heavy doors with hinge and latch of wrought iron, close upon guests who are called at meals by the chimes of mission bells as the monks were summoned to matins. The roof of the old building is covered with moss-grown, century-old tiles from the old Palo rancheris at Temecula, known to all readers of Helen Hunt Jackson's "Ramona."

Within, the mission effect has been carried out in the highest artistry, with unobtrusive comfort, leaving the old design and enhancing the beauty of every room. About the house are semi-tropic gardens with colonnades of graceful arches, with paved walks and wells and bells and constant reminders of an old world atmosphere in which, it must be confessed, the intrusion of modern chefs and up-to-date hotel service does not destroy the illusion.

GLENWOOD MISSION INN, RIVERSIDE, CAL.

The crowning feature of the Mission Inn is the $200,000 cloister addition, recently completed. The exterior is a copy of Carmel and San Gabriel missions; within the massive walls are a music room seating 500, a great cathedral pipe organ; costly stained glass windows, an interior cloistered walk with statues and paintings commemorating the life and work of the old padres, a banquet room, and the private offices. "The Garden of Bells," where hangs the famous Glenwood collection, is used as a tea room. The San Juan Capistrano dome, rising above it, contains the echo organ. Surmounting the cloister roof is the Carmel tower, which contains camera obscura and telescope, affording views of the valley and mountains that one cannot soon forget.

When it comes to mission residences, I believe the winter home of A. C. Burrage, of Boston, at Redlands, easily takes first place. It is located on a hill, near Smiley Heights, and offers a remarkable panoramic outlook over the groves and Sierra Madre mountains from nearly every room in the unique building, which covers 136 by 141 feet. There are twenty-four outside rooms, nine bathrooms, a dreamy patio 28 by 32 feet, and nearly 6,000 square feet of piazza. Thatched summer houses and cosy arbors are scattered about amid orange trees. On either side of the principal drive through the extensive grounds in a bewildering variety of cactii, palms and pepper trees with a background of Ophir and Cherokee roses that are banked up from ten to twenty feet high.

For recreation, there is a swimming pool that cost $6,000, tennis courts, croquet and polo grounds. The latter overlooks San Timoteo Canyon 300 feet below and is said to be the finest in the state. An embankment eight feet high, covered with the midday flowering Mesembryanthemem, backed up by a row of more than 200 pepper trees, surrounds the grounds.

It would be difficult to picture a more beautiful spot than Mr. Burrage's mission home, which is becoming almost as famous as the historical mission ruins.

Los Angeles has many notable mission homes. One that is especially admired is "The Bivouac," the mission renaissance home of Harrison Gray Otis, soldier, litterateur, and owner of the Los Angeles Times. It is charmingly located on rising ground on Wilshire boulevard, Westlake, near the westerly margin of the lake and looks very attractive in its verdant setting of blossoming trees, shrubs and flowers. It was partially completed before General Otis sailed for the Philippines at the beginning of the Spanish War and was finished during his absence under the supervision of John P. Krepel.

The front entrance to "The Bivouac" is through a spacious peristyle. The wing on the north side is especially notable, the lower portion being built in the form of an open arcade, somewhat resembling an Italian garden, "half revealing, half disclosing," so to speak. In the upper story is the General's den containing an interesting collection of arms, armor, war relics, pictures, curios, etc., from various parts of the world. On the west side of the house is a large marque. An awning covers it and on pleasant evenings it is a most delightful place in which to idle an hour or so after dinner. Another feature is the solarium, bright with sunshine and flowers. The cost to date of General Otis' home has been a little over $60,000, of which about $35,000 has been expended for construction of the house proper. The remainder has been used for land, carriage house, and ornamentation of grounds and furnishings.

(To be continued.)

"THE BIVOUAC." RESIDENCE OF GENERAL HARRISON GRAY OTIS AT LOS ANGELES, CAL.

THE USE OF THE STEEL SQUARE—No. 3

By J. B. H.

THE span roof is so called because it spans the building from wall to wall, and although there is more in it than in the lean-to, it still follows that the ordinary span roof is an exceedingly simple one. As far as the present article is concerned, the roof consists of wall plates, rafters, and ridge only, as in Figs. 13 and 14; but in practice it needs ties of some kind to prevent spreading when the weight of the covering material is on. These ties in a house would take the form of ceiling joists, or in an open shed they would be simply timbers fixed across from one wall plate to another, or they might be iron rods with nuts screwed on at each

FIG. 11.—ADJUSTING THE GAUGE.

end. In either case they do not concern the matter in hand at present, therefore they do not appear in the drawings.

A section of the span roof is given in Fig. 15, drawn to what is usually termed "slate" pitch, this being equal to 30 degrees from the wall-plate level. Slates, when laid to the correct lap, will keep the wet out at this pitch, unless in very exposed situations, when it is best to have the pitch somewhat sharper. In any case, it is better to err on the side of steepness, rather than to make a roof too flat. The section has been shown divided into the theoretical

FIG. 12.—MARKING THE RAFTER.

parallelograms as in a previous article, and it will be seen that the height of these is far less in proportion to the width than in the lean-to roof dealt with before.

The width of the roof as shown to the outside of the wall plates is 15 feet and the height from the top of the wall plates to the top of the ridge is 4 feet 6 inches, so that for the purpose of setting out the length and bevels of the rafters there is a width of 7 feet 6 inches by a height of 4 feet 6 inches, or, when the portion

of the rafter above the backing line is taken off (as mentioned in Article I) 4 feet 4 inches only.

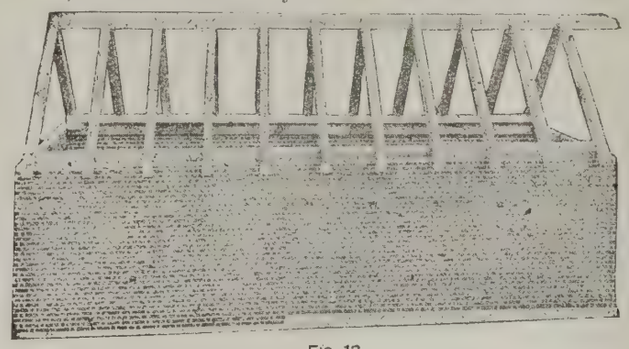

FIG. 13

These dimensions, when divided up into convenient sections, will give us eight spaces of 11¼ inches on the long part of the square, and the same number of spaces in height, each 6½ inches, as in Fig. 16, thus giving the points necessary to work to in setting out the length. Pass the square along the rafter from point to

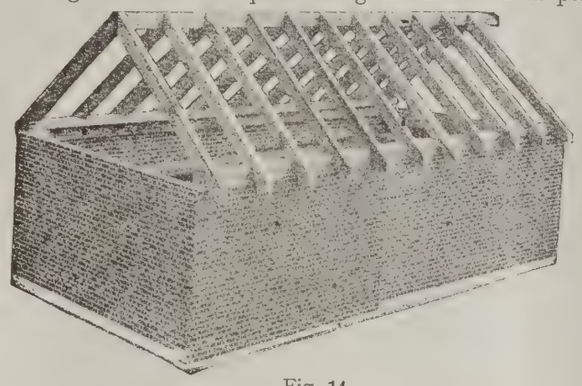

Fig. 14.

point until the eighth is reached, when the short arm of the square will give the upright cut at the ridge.

The vertical cut at the outside of the wall plate is obtained by squaring from the line made by the long part of the square in starting, and the cuts at the foot of the rafters are obtained in the same way, being simply vertical and horizontal, to the same angles as the others, according to the style of finish to be given to the roof at the eaves.

It will be noticed that the extreme middle of the building has been taken in setting out the rafter, entirely ignoring the thickness

FIG. 15

of the ridge. Although this is not correct theoretically, it is so in practice; the half thickness only of the ridge, which is all that is involved, is so little when it is divided up, that it makes no difference whatever in the fitting of the rafters.

It should be understood that it is not intended to set out every rafter in a roof with the square. One only is set out in the way described, and this one is used as a pattern for the others. It may

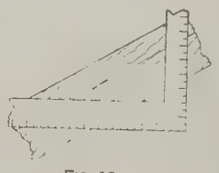

FIG. 16

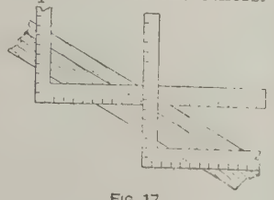

FIG. 17

be added that while the method given is a perfectly reliable one, it is much the better plan, until one gets accustomed to the use of the square, to cut one pair of rafters, and then to test them in position, so as to make sure that they are correct before cutting the whole number. This recommendation is made, not for the sake of testing the method of using the square, but to test the worker's ability in the application of the method. When the latter is thoroughly understood, not only in theory, but in practice, the above test may be omitted.

SCIENTIFIC COST RECORDS IN CONSTRUCTION WORK

IGNORANCE of real costs is a danger whose seriousness every contractor will appreciate. What is less clearly appreciated is the extent to which real costs are not known, and the degree to which construction estimates are based on gravely unreliable data. Discussing this matter, Sanford E. Thompson, consulting engineer, who has been associated for years with Frederick W. Taylor, the pioneer in scientific management says:

Besides of being of use as a preliminary step toward the introduction of scientific management, cost keeping, that is, cost determination of work in progress, is of value to the engineer for making up estimates and checking the work of the builder, and to the builder in bidding on subsequent contracts and keeping track of the cost of the work as it progresses from day to day. In construction work based on the principle of cost-plus-a-fixed sum, and other similar systems, the accurate recording of detail costs on different parts of the work is absolutely essential for submitting the accounts to the owners.

To accomplish any of these aims, the cost records must be accurate enough to serve:

(1) As records for estimating cost of subsequent jobs.
(2) For immediate use.
  (a) To determine whether the builder is making or losing money.
  (b) To fix any point of loss or of too small profit.
  (c) As an incentive to the foreman and workman.

As generally practiced, cost keeping is so approximate and inaccurate as to be of comparatively little value for any of these purposes.

The point just made may be illustrated simply by a comparison of the methods now usually employed in estimating materials and labor. In estimating materials the engineer or contractor notes every item, usually taking the schedule from the plans, and by adding a percentage for contingencies reaches a total which will check fairly well with the actual subsequent cost. Before he starts to do any work, he must order the required amount of each material separately, and the cost of each item is carefully looked into to see that the lowest figures are obtained consistent with the quality of the work required.

With labor, on the other hand, the plan heretofore adopted has been largely a system of guess work. Frequently one hundred or more carefully tabulated material items are set down while the estimate for labor is given in one lump sum, and yet the labor may amount to one-fourth or one-third the sum total of the materials. The variation in the actual cost of the labor from that given in the estimate almost always makes the difference between a profit and a loss to the contractor. These "guesses" at labor costs are commonly excused because it is claimed that the work done by different workmen varies to a great extent, or that it is impossible to provide for unforeseen contingencies. This, however, is merely dodging the whole responsibility. The real reason for such approximations is that the contractor usually does not know the time and cost of doing each kind of work with any degree of accuracy; and the fact is only just coming to be recognized that it is possible to determine in advance how fast each element of the work should be done nearly as accurately as the cost of supplies and materials are now determined, and that once having the fundamental data, it is possible to estimate labor nearly as accurately as material.

HOW TO CLEAN WINDOWS

Windows that show no streaks—that are clean and bright looking—are business pullers in every sense of the word. There is a right and a wrong way to wash windows. The work should be done on a dull day, for when the sun shines on windows, it causes them to dry streaky, no matter how much they may be rubbed.

Before washing the windows, dust them off well, both inside and out, then wash all the inside woodwork. The windows should be washed carefully with warm water, to which a little ammonia has been added. Soap should never be used. A small cloth on the end of a pointed stick is a very valuable instrument to get the dust out of the corners.

When the windows have been washed thoroughly, wipe them dry with a piece of cotton cloth. It is never good to use a linen cloth, as linen will leave a great amount of lint on the glass. When the windows are thoroughly dry, polish them with tissue paper or old newspaper.—Selling Power.

LEAVES FROM A STUDENT'S NOTEBOOK—No. 3

By GEO. METSON

DESIGNING PLATE OR BUILT UP GIRDERS.

THE simplest method is to design the flanges of the sectional area required to resist the compressional and tensional stresses, leaving the web of sufficient sectional area to resist the shear stress. This is not exactly true, but as a large factor of safety is employed, it is sufficiently true for all practical purposes, providing that every care has been taken in accurately calculating the stresses.

The "effective depth" and the "effective span" must be worked with. The "effective depth" can be taken as the height of the web, the horizontal areas of the angle being taken as part of the stress area of the flanges. The "effective span" is the clear span plus one length of bearing as shown in Fig. 1.

The usual depth of a built-up plate girder is 1-12 of its span, though it may vary from 1/8 to 1-16 of the span if circumstances require a deeper or a shallower girder. Its width may vary from 1-20 to 1-40 the span.

EXAMPLE: Let it be required to design a plate girder to carry a distributed load of two tons per lineal foot over a clear span of 22 ft., and assuming that this load includes the weight of the girder itself.

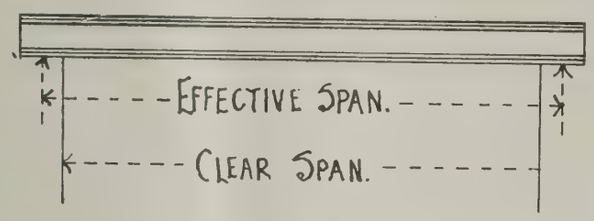

FIG. 1.

SOLUTION: The load on one abutment is approximately $\frac{1}{2} \times 22$ ft. $\times 2$ tons $= 22$ tons, but to this must be added the load on that portion of the girder that is actually on the one abutment (clear span plus one bearing equal effective span). It is first then necessary to approximately arrive at what length of bearing is required. The stone template will safely carry 12 tons per foot super if of good hard stone (the best stone will take as much as 15 tons to the sq. ft.) so that the actual girder bearing must be:

$$\frac{22 \text{ tons} + \text{load on actual bearing}}{12 \text{ tons.}} = \text{say 2 sq. ft. in area.}$$

Assume the width of the girder to be 1-24 of the effective span; it will then be 1-24 of (22 ft. plus one bearing) equal, say 12 in. From this, then, the actual length of girder bearing will be:

$$\frac{2 \text{ sq. ft.}}{12 \text{ in.}} = 24 \text{ in.}$$

The "effective span" will therefore be 22 ft. + 24 in. = 24 ft. The designing can now be proceeded with.

It is first necessary to find the maximum stress resulting from the loading. For a distributed load the formula $\frac{WL}{8}$ will give the maximum bending moment (M. B. M.), and this divided by the effective depth will give the maximum stress.

In the example under consideration the M. B. M. or

$$\frac{WL}{8} = \frac{48 \text{ tons} \times 24 \text{ ft.}}{8} = 144 \text{ tons feet.}$$

Taking the effective depth as 1-12 span, the depth will be 24 in. The maximum stress will then be

$$\frac{144 \times 12 \text{ in.}}{24 \text{ in.}} = 72 \text{ tons.}$$

Taking the design of the compressional flange first and using the safe resistance to compression of 6½ tons per square inch for mild steel, we shall require a sectional area of $\frac{72 \text{ tons}}{6\frac{1}{2} \text{ tons}}$ or 11 1-13 square inches.

The horizontal area of the angles will yield some of this area. Assuming ½-inch plate is being used, the angles will be 3 in. x 3 in. x ½ in., allowing the width of these to be from six to ten times the thickness of the plates connected up. The stress area of the horizontal arms of these angles will be 2 x 3 in. x ½ in. = 3 square inches, leaving 11 1-13 or 8 1-13 square inches for the actual plates in the flange; but the width of the flange is to be 12 inches, therefore $8\ 1\text{-}13 - 12 = \frac{21}{31}$, say ¾-inch, must be the thickness of the metal in the top flange, which can be made up of one ½-inch plate next the angles, with one ¼-inch plate on top.

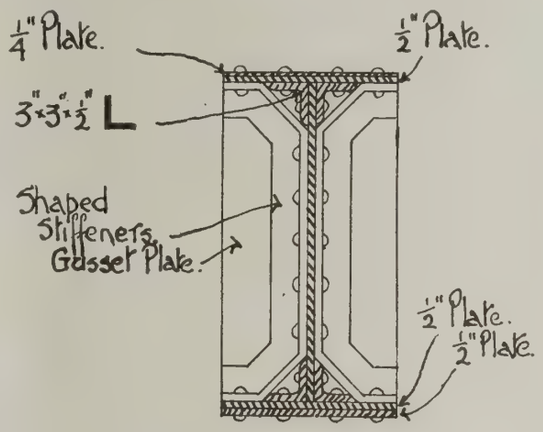

FIG. 2.

In the bottom or tensional flange we must deduct the rivet holes, so that of the 11 1-13 square inches required, the angles, using ¾-inch rivets to the drilled holes, will yield only $2 \times (3 \text{ in.} - \frac{13}{16}) \times \frac{1}{2}$ in. = 2 3-16 square inches, leaving $11\ 1\text{-}13 - 2\ 3\text{-}16$ or $8\frac{166}{208}$; say 8¾ square inches for the actual flange plates, but these, also owing to rivet holes, will only have an effective width of $12 - (4 \times 13/16) = 8\frac{3}{4}$ inches, so that the thickness of these plates must be $\frac{8\frac{3}{4}}{8\frac{3}{4}} = 1$ inch, which would be made up of two ½-inch plates.

Stiffeners at intervals would be required. The girder will then be as in Fig. 2.

In practice, however, it is usual to design, when dealing with steel, the bottom flange first and to make the top or compressional flange equal to it. When dealing with wrought iron plate girders, however, the compressional flange must of course be calculated for separately, but wrought iron for constructional metal work is now almost entirely superceded by mild steel.

The Commonwealth Government having selected Canberra, in New South Wales, as the site of the proposed Federal capital, it has been decided to invite competitive designs for laying it out from all parts of the British Empire. In anticipation of this an elaborate survey has been commenced. The boundaries of the new Federal territory will first be delimited, and then a contour survey of the city proper made. When this has been completed lithographic plans will be printed and sent to all parts of the Empire, with the fullest information for intending competitors, who will have to make provision for the location respectively of the viceregal residence, Parliamentary buildings, public offices, university, military barracks, and other groups of buildings. The site, which is one of the most beautiful in Australia, affords abundant facilities for the construction of one of the finest modern cities in the world.

PERFORMANCE OF BUILDING CONTRACTS

By W. J. STANTON

The work done under a building contract is generally of such a nature that it is beneficial to the owner of the land, even though it has not been done in strict conformity with the plans and specifications. An exception to the ordinary rule applicable to written contracts, that the parties must fully comply with the terms thereof, has been created with respect to building contracts by what is called the rule of substantial performance. Approximate justice is awarded in such cases by the application of the doctrine of substantial performance, under which the contractor is allowed to recover the contract price less a deduction for the damage caused by omissions or defects.

In respect to building contracts the rule is well established that where a contractor who has endeavored to perform his contract in good faith has done so except as to unimportant deviations, omissions, or defects which are not intentional or willful, but the result of mistake or inadvertence, he may recover as for a substantial performance. The reason for this construction of such contracts is in part the difficulty of obtaining perfection in the quality of the materials and workmanship, and of entirely correcting the effect of a slight inadvertence, and the injustice of allowing the owner to retain without compensation the benefit of a building upon his land, that is substantially, but not exactly, such as he agreed to pay for. Under this rule each party obtains what he is equitably entitled to—the contractor, payment for all that he did, and the owner, compensation for all that the contractor omitted to do.

The rule of substantial performance cannot be invoked where the omissions or defects from the requirements set forth in the building contract are intentional and not the result of an attempt in good faith to perform the contract. Where the defects or omissions are of such a character as to be capable of being remedied, the proper rule for measuring the amount recoverable by the contractor is the contract price less the reasonable cost of remedying the defects or omissions so as to make the building conform to the contract. The object of the rule is to give to the owner in substance as near as practicable the very thing contracted for, not merely in value, but in form and character. In a case before the supreme court of Wisconsin, the rule is stated as follows: "In case of entire neglect to furnish an item of labor or material, or in case of a defect which may be easily remedied without taking down and reconstructing a substantial portion of the building, this allowance should equal the reasonable expense of supplying or correcting the defect. In case of a defect which could only be remedied by taking down and reconstructing some substantial portion of the building, the allowance should be for the amount which the building is worth less, by reason of the defect, than the contract price."

Where the defect is one which cannot be remedied without depriving the contractor of adequate compensation for his labor and material, his measure of recovery is the difference between the value of the building as completed and the building as it ought to have been completed.

The defects occurring in the building must not run through the whole of it or be so essential that the object of the parties to have a specified amount of work done in a particular way is not accomplished. In a New York case the contract was held not substantially performed by reason of the substitution of material for various details of the house, such as sheathing, building paper, sash cords, plumbing supplies and the like. In another New York case the same rule was followed where earthen sewer pipes of a smaller size were used instead of iron pipes of a larger size as called for in the specifications. Where a contract calls for the furnishing of a particular kind of marble columns from a certain country, which can be procured, the substitution of columns which are substantially like them is not substantial performance.

Deviations from strict performance should be allowed with caution. The owner of the building has a right to choose for himself what he wishes constructed, and should not be compelled to receive something else. In the matter of the decoration of buildings mere taste or preference approaching almost to whim might be controlling with the owner, and therefore the substance of the contract. This is particularly true of contracts involving the painting of buildings. Thus where the subject matter of the contract involves questions of personal taste, the contract is construed so as to require strict performance to the satisfaction of the builder.

Where both the ceiling of a store building and the ceiling of the cellar thereunder are considerably lower than called for in the specifications, and stone foundations are omitted under the party walls, it cannot be said that there is a substantial performance of the contract. In a case before the supreme court of California, brought to recover on a building contract, the plans and specifications did not state where the windows of a basement story which was to be placed underneath a building after raising it were to be placed. It was held that the fact that they were not placed in alignment with those in the upper story did not prevent the contractor from recovering for a substantial performance, where the cost of remedying the defect was between seven and eight dollars, and they were so placed in order to afford more furniture space in the room. The fact that the roof of a rear addition was built five inches lower than called for in the plans was held not to be such a deviation as would prevent the contractor from recovering for a substantial performance, as the change did not affect the usefulness or symmetrical appearance of the house.

Where a contract required the construction of a sawmill fifty feet by one hundred and fifty feet, it was held that the construction of one which was seventy-eight feet by one hundred feet was not a substantial compliance, even though it cost more and was of greater value and better adapted to the purposes to be accomplished. Where a contract called for "No. 1 rustic and the best quality of joist studding," the use of No. 2 rustic and second quality of joist and studding was held not to be a substantial performance. Where a contract required the furnishing of only "⅝-inch beaded yellow pine first standard ceiling" and first and second grade "long leaf yellow pine flooring, not over 3¾ inches wide," the furnishings of a much less expensive and altogether different kind of pine ceiling and flooring was held not to be a substantial performance, even though the lumber furnished was as good and durable for that specific work, since the difference in finish and appearance between the two kinds of lumber may have been important. Where a contract required the putting in of parquet floorings in a first class manner, the placing of such flooring in such manner that spaces existed between the blocks by reason of the blocks shrinking through not being properly seasoned and exposed to the rain in being hauled to the house, was held not a substantial compliance with the contract. Where clapboards were used in the gables and boards which were wider than those specified in the contract, it was held to constitute a substantial performance where the usefulness and value of the house was not impaired and the difference in the cost of the material substituted did not exceed $50.

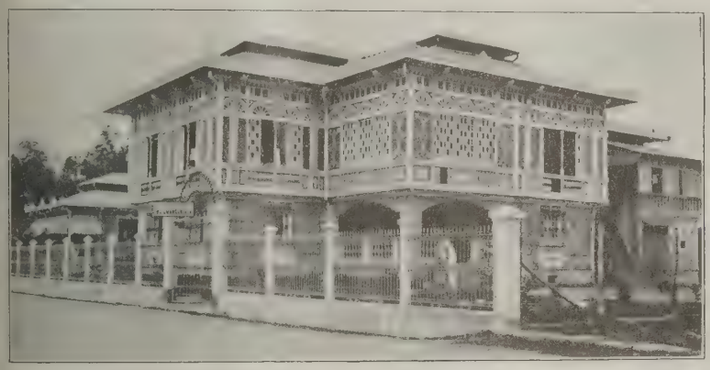
SUPREME COURT DECISIONS

A building contract made the architect the arbitrator between the parties on the question of performance. The Supreme Court of New Jersey holds that the burden was on the defendant in an action on the contract to show fraud of the architect, or mistake by him, relating to the matters certified. The case also holds that in the absence of fraud or palpable mistake on the part of the architect in giving the certificate required by a building contract, such certificate is conclusive on the owner.

A contractor for the construction of a building guaranteed that the workmanship should be first class, and a granolithic floor put in by a sub-contractor was soft and defective. The Supreme Court of Appeals of Virginia held that the term "Workmanship" as used in such guaranty was sufficient to protect the owner against bad or unsuitable materials by a sub-contractor, and the owner's measure of damages was such sum as it would reasonably take to make the floor conform to the contract.

The Court of Appeals of Georgia holds that under an act passed in 1906, the application on which an insurance policy is based is not to be considered as part of the policy or contract between the parties, unless a copy thereof is attached to or accompanies the policy. Statements made in the application are not to be treated as warranties or covenants, on account of the failure or falsity of which the policy may be avoided, unless a copy of the application is attached to the policy or accompanies it, though representations contained in the application, if fraudulently made, may give to the insurance company the right to avoid the policy.

THE MANSION OF A NATIVE NABOB



By MONROE WOOLLEY

In many ways the Filipinos show that all of them are not of the type of wild hill tribes usually shown in side-shows and expositions in this country. One of these is in his taste for architectural beauty. Few Americans can associate anything in the form of a Filipino dwelling with things other than the thatched hut shown in the native villages at St. Louis, Seattle, and the other places where they have appeared. Such huts are the domicile at home only of the peasant classes. They do not at all represent the costly, strongly, and handsomely built residences of the metropolii of the archipelago, most of which, if built in this country of the same material, could be afforded only by the well-to-do, if not merely by the wealthy.

Taught by the Spaniard to make home a place of refuge from the busy world as well as a hospitable retreat for friend and strangers, the Filipino spends a very liberal share of his means to this end, perhaps a much larger sum than our own people similarly situated spend for homes on the average. Hence, few Filipinos are renters, even among the poorer classes. In this respect they have one on us. The peasant, stripped of money, takes to the jungle with his bolo, bringing in, maybe in a single day, all he needs to build. The bill of material is not extensive—simply a few bamboo poles, some nipa palms, and not to exceed four hardwood posts. No nails, doors, windows, and the like, are needed. These can all be devised from the material in hand. In the case

THE SALA OR RECEPTION ROOM, WITH A FINE HARDWOOD FLOOR FOR DANCING.

RESIDENCE OF THE HON. MARIANO LINN AT SAN FERNANDO, P. I. THE FIRST FLOOR IS DEVOTED TO THE LAW OFFICES AND SERVANTS' QUARTERS, THE SECOND FLOOR BEING THE RESIDENCE APARTMENTS.

of the peasant's superior fellow-countryman, as before stated, the home generally comes before all else. A great deal of friendly rivalry exists among the middle and high-class citizens in their home building. In this they may be a trifle vain, but the town and the family profit by the fault, if such it may be termed.

Not infrequently the Spanish and native architects evolve some really tasty designs, never, of course, neglecting the details essential to a dwelling suited in all ways to the whims of a tropical climate and the customs of a tropical race.

What is no doubt the finest residence in the many outlying provinces of the archipelago, of which there are nearly as many as there are states in the Union, is that lately completed at a costly figure by the Honorable Mariano Lim, a native lawyer, at San Fernando, Pampanga, north of Manila.

Indeed there are few houses in the capital and possibly none whatever in the other large cities of the group which excel this palatial home. Not that the house cost so fancy a figure in dollars and cents compared to some of the homes of our millionaires, for it did not. Yet when the differences in construction are noted this native mansion might compare favorably in point of cost with many famous country seats in this country. In the Philippines even the fine houses are mere shells of finely polished hardwood. Lath, plaster, and costly decoration as we know it are not a part of the scheme, nor are these things necessary.

Mr. Lim's house, containing as many apartments as a small hotel, is constructed of concrete and highly polished, hand-carved native hardwoods of which the Philippines boast the finest in the world with an almost inexhaustible supply. The ground floor is of concrete, as common in most of the pretentious houses of the land. Molave, narra, and ipil, a triumvirate of the most beautiful hardwoods, figure in the upper construction. The house alone, for material and labor, cost twenty-one thousand dollars. As the Filipino carpenter gets about twenty-five cents per day it will be readily seen that in other climes this item alone would have been easily doubled or trebled. Again the material of which this house is made, imported into the United States, would cost about two or three times as much as it cost Mr. Lim. The first floor of the *casa de* Lim, besides containing quarters for a retinue of negrito servants, provides in addition spacious law and editorial offices for the owner and his associates in law and journalism. Mr. Lim has his printing establishment and newspaper next door. Fitted primarily for business, and with a very business look about them, these offices are at the same time exceedingly handsomely appointed and appropriately furnished. A feature is an electric call bell system between the different offices.

Upstairs in the residence apartments a long *sala* with its brilliantly polished hardwood floor invites the light fantastic and where from eighty to one hundred couples may trip to the strains of Mr. Lim's light fingered native orchestra. Something almost entirely novel in this elaborate mansion nestling far in the interior of Pampanga province, is running water, furnished for all purposes throughout, and the source of which is artesian.

THE SALON DE HONOR OR DRAWING ROOM.

When this splendid provincial home was first formally thrown open with great *éclat* not so long ago there were present some four or five hundred guests, including a number of leading Filipinos and Americans. Manila society was well represented, a special coach on the Manila & Dagupan Railroad having been placed by the generous host at the disposition of the visitors from town.

GYPSUM AS A BUILDING MATERIAL

By GEORGE E. WALSH

THE extent to which gypsum is used in modern building trades may be illustrated by the tremendous strides made in recent years in the mining and manufacturing of this material, and the fact that 90 per cent of the output is used directly or indirectly in the building of new and old structures. The annual output of gypsum approximates a value of $25,000,000, and the rate of increase each year is nearly 20 per cent. The discovery of new methods of utilizing gypsum, and the invention of new machinery and processes for manufacturing it into commercial forms, are responsible for its increased output.

In the modern building movement every effort is being made to minimize the danger from fire and to substitute so far as possible manufactured "lumber" for wood. The increasing cost of lumber, and our diminishing forests, make it essential that substitutes for wood be used to an ever increasing extent. In other words we are building faster than the supply of lumber increases, and to conserve our forests we must use materials other than wood for general construction purposes.

Gypsum in some of its manufactured forms serves a most important factor in both of these fields. It is sufficiently fire-resisting to make it of the utmost use in buildings, and cheap, abundant and serviceable enough to make it a good substitute for lumber in innumerable cases. Gypsum is light in weight, strong, and easily worked into any shape desired. Added to these qualities are others such as low conductivity of heat, and great resistance to water under fire conditions.

The most common ways of using gypsum for fireproofing is in the form of plaster boards, tiles, wall furring, partition blocks and for the covering of columns and beams. Plaster board made of gypsum is made in one-quarter to half an inch thickness, and from 32 to 36 inches in width and length. These boards designed at first to take the place of wood lath are today used extensively for partitions and for walls as well as for ceilings and the sides of furnace rooms. They are light in weight and very tough, and can be nailed directly to studding and joists.

There are two distinct varieties of gypsum or plaster of Paris used in the building industries. One is stucco plaster, which is quick-setting, and the other building or hydraulic plaster, which is slow setting. Stucco plaster is burned at a low temperature, and it still contains a good deal of the original water of crystallization. In the ceramic industries plaster of Paris is used extensively, but in the construction of temporary houses, such as those built for fairs and exhibitions, adulterants are employed to a large extent. Lime and sand together, or layers of mixture overcoated with pure gypsum, are commonly used, the plaster sometimes running as low as 20 per cent by weight. In working in quantities of sharp sand, the strength of the mass is often increased by the addition of glue to the water and by the mixing of cow's hair or other fibrous material.

In making stucco plaster and plaster board for partitions and even outside walls in recent years wire cloth with more or less open mesh is used as a reinforcement or core. The wire cloth is coated on one or both sides with the gypsum, and the board becomes firm and rigid for building purposes. Sand, lime, ashes, cocoa fibre, excelsior, hair, rushes, hoop iron and metal shavings have all been employed as binders for gypsum boards, and as a result great variations in the industry may be noted.

As in the employment of cement, the use of gypsum has sometimes given a bad account of itself through careless or ignorant manipulation. For instance, coal ashes and old plaster have sometimes been used so that the resultant material easily crumbled and disintegrated. This only gave a bad name to gypsum plaster work, but no more so than concrete has often received through the ignorant or careless mixing and adulterating. Where good materials are used, and good methods of mixing and pressing are employed, gypsum products in their various forms give good satisfaction.

In Europe gypsum flooring tiles have been used to some extent in buildings where the tramping is not hard or severe, such as in storage houses. Plaster tiles, even though reinforced with wire metal, have not received much attention in this country. But plaster lumber for partitions are popular and widely used. Millions of tons of gypsum enter into their manufacture every year.

Plaster boards of this nature are lighter than water, and they can be sawed, cut, planed, and fitted as easily as wood, and they hold screws and hooks well. They can be made and used at any season of the year, and when installed they are vermin proof and practically fireproof and almost sound proof.

With the exception of special patented forms of plaster boards, they do not have sufficient compressive strength to make them useful for holding up roofs and upper floors. They are strong enough to bear up their own weight, but cannot be used like bricks in wall for carrying loads. A partition made of plaster that must carry a special load is built up of stucco and hydraulic gypsum reinforced with metal or wire lath. A good deal of experiment has been carried on in recent years to make satisfactory reinforced plaster material for heavy duty work. But it is doubtful if this material will ever become popular for outer wall construction. In the first place it must be protected from weathering when used for outside wall work. A wash of cement is the most satisfactory protection, although asphalt is used where appearances do not count. The cement wash cannot be applied directly to the plaster, and a preparatory coat of lime wash is first used or a very thin coat of lime plaster.

Gypsum is largely used as an adulterant for asbestos, and frequently 80 per cent of asbestos pipe covering is composed of gypsum. This fact is good evidence that gypsum makes a good fire protection and a fine non-conductor of heat and cold. Gypsum plaster is also an excellent protection for both wood and iron beams and girders in many mills and factories. It keeps the wood from rotting and the iron from rusting. It is not easily affected by acids and dyes, and in a good many establishments, as tanneries, wash-houses and dyeing factories, it is freely used to protect all exposed wood and metal parts.

Probably in factory and mill construction gypsum plaster finds as great a use as anywhere. Appearances do not count so much here, and the rough plaster boards are nailed on to protect the building from fire, rust and decay. It is applied to the walls and ceilings of boiler and furnace rooms and wherever acids and dyes are used. When used for apartments and private houses, the plaster boards are first nailed on and then joints are finished off with a coat of plaster that can be worked to a smooth surface. Plaster boards are made generally with a smooth and rough surface. The latter is placed outside so as to receive a finishing coat when the walls and partitions are all up and the trim nailed on.

Where partitions are made entirely of plaster boards, they are usually nailed to the vertical studding, but often they are used without studding at all. In such cases they have to be reinforced in some way. For temporary structures there is no material so cheap or satisfactory as plaster boards. The trade is enormous for this work. The plaster boards are then stiffened by using rushes, twigs, straw and other material laid lengthwise. When twigs are used, they must be soaked in water first to prevent their cracking the stucco when exposed to wet weather after being embedded in the plaster. Small twigs are better than big ones.

Plaster boards of this nature are usually laid in double layers, one layer running vertically and the other horizontally. Sometimes an air space is left between to increase the non-conductivity of heat and cold. A certain amount of studding must be used to support the boards, but only sufficient to keep them in place. The saving in studding is thus quite considerable. Barns, garages, and similar small buildings are made with great success in this way.

The use of stucco plaster boards for roofs has increased in recent years, and all sorts of methods have been employed to make them satisfactory. If rightly used they prove very durable and useful. The stucco plaster boards are nailed to light rafters. Very thin boards are employed for this purpose, and on top of this a three-quarter-inch layer of gypsum beton is laid, consisting of stucco plaster with either sharp sand or good sharp, screened coal ashes. Finally a layer of asphalt roofing paper is placed on the roof, and strewed with sand or fine gravel while the paint is still wet. For comparatively flat roofs this makes an excellent covering. It is very light, durable and fireproof. It will also protect the inside to a remarkable extent from the heat of the sun. Contractors' buildings put up in the tropics with such a roof protection are very popular.

In Germany a good deal of plaster board is made at the factories with galvanized woven wire or expanded metal as the core or reinforcement. The wire cloth is stretched between standards, and a mixture of gypsum and lime is applied to both sides with

cow hair or other substance as a binder. Partitions with an air space between are also made in this way. Two layers of wire cloth are then used, with a space between, and then plastered on each side. Partitions of this nature are made ready for setting up in buildings.

Gypsum plaster is applied both to wooden lath and metal lath in many of our modern buildings. When plastered on wood lath about one-third of the material is worked through the interstices to form keys or clinches. On wire or expanded metal lath even a greater amount goes into the formation of the keys. There is a great saving of the material when manufactured in plaster boards, for there are no keys necessary, and nearly all of the material is formed in a compact mass outside. When plaster boards are put up, with a rough surface exposed, it requires comparatively little plaster to finish off a smooth surface. Usually a quarter of an inch of plaster on the boards makes a perfect finish that is less liable to break or crack than any other method of wall construction. Usually in nailing on the boards they are spaced a quarter to a third of an inch apart so that the gypsum mortar used as a finish will fill these spaces to act as a sort of key or anchor to the whole surface. The boards are thus all joined together in one homogeneous mass that cannot easily crack.

The increase in the manufacturing of "lumber" for general house construction is dependent to some extent upon the distribution of the materials used in the work. The cost of lumber in many parts of the country far removed from the vicinity of the forests is high because of the excessive transportation charges. This same cost would apply to all other building materials if they were not equitably distributed throughout the country.

In the case of clay products an advantage is obtained in having clay deposits in nearly every state. Consequently they can be made for each section of country without long shipments. The same holds true of gypsum. While our largest supplies of gypsum come from a few states, there are abundant deposits in New York, Ohio, Michigan, Iowa, Oklahoma, Kansas, Colorado, South Dakota, Montana, California and other states. This general distribution of the material permits of the manufacture of gypsum plaster boards in many parts of the country, and the industry of making artificial fireproof lumber of this character is growing rapidly. It is used today more and more in cities and the country, and builders are utilizing it in hundreds of different ways never dreamed of a few years ago. As a factor in the building trades of the future it must be reckoned with, and builders and contractors must familiarize themselves with its various uses and application to keep abreast of the developments of their profession.

A SAMPLE SPECIFICATION—By S. CHARLES, C. E.

The facing of all basement walls above grade line to be of Port Deposit granite, rock face broken range, with squared beds, builds, and 2-inch pitched points, securely bonded to backing and laid with neat raised joints. No stone to be less than 8 inches on the bed. Reveals, soffits and jambs to be fine axed.

The rock facing of ashlar must not exceed 1½ inches in projection and to be free from iron tool marks, drill holes and other defects.

All exterior walls, from concrete footings to finished grade line, must be plastered with Portland cement mortar ¾ of an inch thick.

The mason will assist the carpenter to set all door and window frames and see that they are kept well braced and are built solidly in the walls. All crevices to be filled with mortar.

Coping along sidewalls as shown on drawings shall be built in a manner as specified for walls, except the cap-stones shall be 4 inches wider than the thickness of the wall and shall generally extend entirely through the wall. Coping shall extend to a depth of 3 feet below the line of the finished wall.

Gate stones shall be built in the same manner as coping, except every alternate stone shall be of the size of the required post.

All basement piers shall be of the size noted on the drawings and every alternate stone course shall extend entirely through the pier; capstone shall be in one piece, set perfectly level and at the proper level to receive the girders.

All walls must be covered and protected from storms, braced and stayed during the progress of construction and thoroughly cleaned down at completion.

CUT STONE WORK.

All stone work above basement, as both water tables, bases and caps of pedestals, bases and caps of pilasters, rails, balusters and columns for porch, and all window sills, as indicated on plans, to be of Indiana limestone of first-class quality and fine texture, sound, strong and free from stains and discolorations.

All carving and moulding must be done in an artistic manner from detailed drawings furnished by the architect. Mouldings to be cut straight and true, and set perfectly straight at joints. All columns to be cut in one length as detailed. All the Indiana limestone work shall be uniformly tooled, in a manner known to the trade as square drove work—6 bats to the inch. No horizontal or vertical joint shall be more than 3/16 inch in thickness. Patching of stone work will not be allowed, except on very large stones, and then only at the approval of the architect.

All exterior door sills and all exterior steps and platforms to be of granite of the first quality and fine axed, cut as detailed with the required lugs and washes.

Basement window sills to be slip sills of Port Deposit granite, two brick courses in thickness, rock face, and surface fine axed.

All steps and platforms to be of the required thickness, as shown on plans, and in one length where possible.

All door sills to be 8 inches thickness, cut with wash and to extend the whole thickness of wall and 1½ inches outside of reveals.

Window sills to be two courses of brick in thickness, cut with wash, and to extend 1½ inches outside of reveals and at least 2 inches under outer edge of sub-sills. Sills to be bedded on ends only.

All chimneys to have cap of blue limestone, 6 inches thick in one piece, tooled to true surface, and flues cut through.

All area walls to be capped with blue limestone, covering the entire wall and extending 1 inch on each side of wall. Cut wash and drip as detailed.

Arrises to be squared and surfaces fine axed. Joints to be secured with galvanized iron clamps leaded into stone. All stone delivered on the job shall be protected both before and after erection and any defective stone shall be removed from the premises. Every stone must be carefully set and leveled in full bed of mortar of uniform thickness, not thicker than hereinbefore specified. Stone having a greater build than 12 inches shall be anchored every 3 feet with heavy galvanized iron anchors extending through the wall. All projecting stone work shall be securely anchored as detailed or as directed by the architect.

Upon the completion of the work, the entire stone work must be cleaned down with steel brushes, all joints raked out and pointed up with the best La Farge or Puzzolana cement and clean white sand, and everything finished in a first-class and thorough, workmanlike manner.

Mortar for stone work below water table to be of one part approved Portland cement, and three parts clean, sharp sand, free from loam or other impurities. Sufficient cement must be kept on the ground to permit the architect to test each barrel as to its strength before using. All outside walls, when coming in contact with the ground, to be plastered to grade line with a good coat of Portland cement mortar. Mortar for Indiana limestone to be two parts freshly burned lump lime and three parts sand, as hereinbefore specified.

BRICK WORK.

All walls from bottom of lower water table, piers for porches, partition walls as indicated on the drawings, and all chimneys, to be built of sound, hard, well-burned common brick, of a quality approved by the architect.

The contractor will be required to furnish samples of brick he proposes to use before commencing work, for the approval of the architect.

All brick to be moistened if laid in dry, warm weather. All joints to be thoroughly filled and slushed with mortar, leaving no empty spaces.

All walls and piers to be carefully built, perfectly straight and plumb and to true lines on all faces, leveled at proper point to receive all framing. All walls are to be properly bonded every fifth course with a row of headers around entire building. No walls to be carried more than 5 feet above those adjacent, during the progress of construction, and to be covered and protected from storms, braced and stayed. (To be Continued.)

DEVELOPMENT OF GASOLINE ENGINES

By JOSEPH C. RILEY

ASSISTANT PROFESSOR OF MECHANICAL ENGINEERING, MASS. INST. TECH., BOSTON

Presented before the Congress of Technology at the Fiftieth Anniversary of the Granting of the Charter of the Massachusetts Institute of Technology.

* * *

The development of the gasoline engine has been more rapid than that of any other form of motor, not even excepting the steam turbine. We all recollect, not many years ago, with what curiosity we regarded the new horseless carriages upon our streets, and how we wondered whether the noisy little engines which left a smell of half-burned gasoline behind them, would ever become really desirable motors. As late as 1896, a prominent engineer wrote, in his work on the gas engine, that he had recently examined one of the strangely designed vehicles then attracting attention in France, and that in his opinion, ingenious as the carriage was, it would not come into general use unless the gasoline engine with which it was equipped were replaced by a heavy oil engine. That was only fifteen years ago.

The first part of this period of development saw radical changes in the design of these motors, but the use of light-oil had come to stay. Although dangerously inflammable and five times as dear as the heavier grades of petroleum burned in larger oil engines, the cleanliness of gasoline and the ease with which it can be prepared for combustion, are alone sufficient to dictate its use. The original methods of mixing, introducing and firing the explosive charge were soon changed in order to secure more reliable operation throughout a greater range in speed and load. Cylinders and valves were designed to give more power. Ball-bearings and gears of a degree of perfection previously unknown were introduced, to minimize friction. But the most noticeable changes in the last few years have been largely in the nature of improvements in material and processes of manufacture, tending toward a general improvement of the engine as a machine and a simplification of its construction. New alloys of aluminum and methods of cooling them locally in the mould have brought about light, yet rigid and durable castings for frames. New steels have provided stronger shafts and connecting rods. Machine moulding from wax or metal patterns has produced better castings of more uniform thickness and yet at lower cost than could have been produced by hand. The art of moulding the thin walls and coring the irregular jackets of cylinders, and then casting them in iron, has indeed been revolutionized. Castings which a few years ago would have attracted general attention as remarkable specimens of good workmanship are now so common that we pass them by without notice. The use of special jigs for holding work during cutting operations and the application of semi-automatic tools for machining or grinding to precise dimensions have not only produced better fitted surfaces and fully interchangeable parts, but have also reduced the time and cost of production.

The gasoline engine has profited by the general rapid advance in all branches of mechanical work. Its own special improvements have been, for the most part, such as would naturally come from the thousands of ingenious designers, skillful mechanics and experienced drivers, who have tested and tried it under all possible conditions of service, on the road, on the water, and in the air. As a result, advancing by process of trial and error, the engine has reached a fair degree of perfection in two points at least. It has been made to develop greater power per unit weight than any other form of prime mover; and in reliability it has been advanced to the stage which warrants its use even for such exacting service as propelling a life-boat or driving a fire-engine.

Little of this development, however, has been made possible by what may properly be called scientific study of the engine's performance. At first there was scarcely time for such work. The demand for engines was often greater than could be supplied, so the engineers' efforts were concentrated on increasing the factory output as fast as possible, consistent with a fair improvement in the product. It was easy to improve the engine year after year by applying such new inventions as very plainly made it a better machine. The time for refinement in design had not yet come. Thorough trials of an engine with all its accessories were usually carried out to make sure that everything was assembled and adjusted well before the product was sold, but measured tests for anything except the power output—under somewhat uncertain conditions—were not considered necessary. Only the most progressive manufacturers made anything like systematic investigations conducted with sufficient care and skill to discover the effect of change in some one feature of operation or design, and to get data reliable enough to be of real value. Mechanical arrangements were varied by placing the valve at the sides, or in the cylinder heads; pistons were made with short strokes and pistons with strokes of greater proportionate length, with exactly opposite claims of merit put forth by different builders.

Aside from differences in general excellence of mechanical construction caused by such variation in design, unquestionably there are inherent differences in the power developed and in the economy of fuel consumption. A study of the results of tests of automobile engines shows a wide variation in power of motors having similar dimensions and running at the same piston speed. When operated at the piston speed corresponding to maximum power (a speed usually between 1,100 and 1,500 feet per minute), the best engines give results nearly 50 per cent better than the poor ones. Knowing that the engines referred to are developing all that can be got out of them, we may well inquire the cause of this difference in output. But little of it can be charged to imperfection of the mechanism causing surface friction, for even the cheaper motors are well built in this respect. It is influenced by the quality and quantity of explosive mixture, the amount of compression, the time and rapidity of ignition and the timing and size of the valves.

The interrelations of these many factors are very complex, but they may be summarized by saying that the power depends upon the pressure in the cylinder. Gasoline motors like all other heat engines of the reciprocating type operate by expansion of a fluid under pressure. The variation in force as the piston moves in and out is what does the work; the time at which pressure is applied and the rate at which it changes consequently determine the amount of work realized. The more we know about just how the pressure varies the better able we are to devise means for controlling its rise and fall and thereby producing a greater net output. In the early days of steam engineering, information of the rate of pressure change in the cylinder was considered so necessary that Watt invented an instrument for recording it. A modified form of this steam engine indicator has played an important part in the study and improvement of steam engines ever since. With it, the cause of deficient power may readily be traced to its origin in faulty steam distribution, in wire drawing through too small a port, or in condensation; without it the very fact that the power is deficient may remain unsuspected. Any attempt to secure the last refinement in steam engine performance without using the indicator would be like deliberately working in the dark. For internal combustion engines of moderate speed the indicator has been of service, though it was not needed as much as for steam engines. But the full speed of gasoline engines of the classes here considered, namely the light weight motors adapted to automobiles, aeroplanes and small boats, is much too high for any of the ordinary commercial forms of indicators. In Germany and England, half-size indicators of the standard patterns are manufactured and sold for this work. It is said that they can be used up to 1,500 and 2,000 revolutions per minute—which should be understood to mean little more than that they can be operated at such speed without actually breaking. The natural cadence of vibration of their springs and moving parts is altogether too slow for anything like such high speeds; the waves introduced into the diagram by violent explosions would be too long and might be misleading. However, at speeds from 400 to perhaps 800 R. P. M. they are very useful. What is needed is a recording mechanism with a period of vibration of high frequency, more like that of the electrical oscillograph, say between 500 and 1,000 per second; and if incorrect deductions are to be avoided, great care should be taken to insure that the indicator diagram starts from its dead points exactly in phase with the engine piston. (To be Concluded.)

One can do a wide variety of work on a plain bench or table saw, but where there are a multitude of changes and shapes to cut, it generally pays to get one of the variety type of saws built especially for this kind of work.—Exchange.

ARCHITECTURAL CHANGES

By E. P. H.

Considerable change has been made in recent years in the styles of architecture.

Some fifteen years ago a great deal of ornamentation was shown in the way of scroll and spindle work, while now we seldom see any scroll work on any part of the exterior or interior. Turned work is losing favor even for columns and balusters, giving way to plain square materials.

The concrete house, whether solid block, or simply the plastered exterior seems to require the omission of the Colonial columns, which have been in favor for some years past. The porch piers are being built up to the cornice omitting wood columns entirely, while often we see a concrete, brick or stone pier running up balustrade height, and a square box shaft from there up to the box plate.

Strictly Colonial houses are being built in great numbers, some calling for the large plain or fluted columns, with composition caps in one or the other of the various orders. These large shafts being rather expensive are seldom used except in large and expensive residences.

The small Colonial houses show more or less turned work, and even some houses on a Colonial order are rather void of these features, commonly understood as Colonial.

The plain square house with peak or two gable end style seem to prevail, taking place of the former style that called for many gable ends.

The interior finish is plain indeed. The mouldings shown are principally flat to show the hardwood grain. Of course, the finishing of flat hardwoods is easier than if moulded, and the cost has had much to do with the present-day styles. Some years ago when white pine prevailed the interior wood finish on account of its being painted it was thought necessary to have the trim muchly moulded, and even when the hardwoods started to be used it seemed hard for the architects to get away from moulding the interior trim, but as time went on it was soon seen that the hardwoods required flat surfaces to bring out the richness of the grain and then, besides, it is cheaper to apply the filler, stains or varnish as the case may be.

Then, too, people have become mission crazed. This means plain, flat finish. Even broken corners are omitted, but more finish is required to make up the plaster panels and beam work, so the cost is some higher. Therefore, all the change comes about because of the increased cost.

The housewife must have hardwood finish, requires a sideboard, and plenty of pantry cases that were not seen in the old white pine finish home, but which was greatly decorated on the outside with every kind of embellishment.

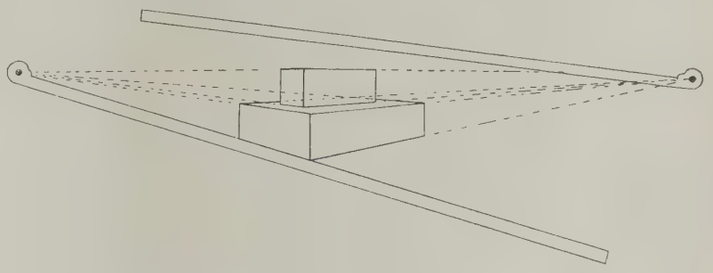
ADAPTABILITY OF OAK FLOORING

Very often architects and contractors use the clear plain (first grade) of oak flooring in many rooms where the select plain (second grade) could be utilized equally as well, at a saving of about 25 per cent in the cost. Select plain (second grade) makes a floor just as serviceable as the clear plain and equally as durable, the principal defect in this grade being sap, which in oak is not considered as serious a defect as in other woods, on account of the tannic condition. The difference in the shading is easily lost sight of in the finishing, by application of a golden oak filler to blend the light and darker pieces. Such a finish would make it very difficult for even an expert to distinguish it from the clear (first grade).

The select plain (second grade) will fill every requirement where a medium priced floor is desired, whether it be in apartment houses and such character of buildings, residences, stores, public buildings, club houses and hotels. This class of buildings requires a high class and serviceable floor. Select plain is highly recommended, as it gives an artistic and durable floor at a very reasonable cost.

Some of the best homes, costing from $7,000 and up, are now using the select plain in the upper floors and very often the entire residence uses this grade throughout.

A little care on the part of the floor layer with this select plain (second grade) will insure a job almost as good as though the clear (first grade) was used. Badly discolored pieces should be utilized for places under the rugs, closets, and other out-of-the-way places.



The select plain oak flooring is manufactured in the 13/16 inch thickness and 3/8 inch thickness. The 3/8 inch thickness select plain without a doubt makes the most economical floor that can be bought. It is tongued, grooved and end-matched. It can be secret nailed and when laid has the appearance of heavy flooring; 3/8 inch thickness should always be laid over a subfloor. In old homes it can be laid over the old floors and in new homes over a cheap subfloor. The 13/16 inch thickness makes the most substantial floor, but it is 30 per cent more expensive than the 3/8 inch thickness. Oak flooring can be had in two colors, white or red. The preference for either, simply resolves itself into a matter of taste, as both have about the same lasting qualities. The white is often preferred, because it runs more uniform in color.

A PERSPECTIVE DRAUGHTING BOARD

By CHAS. CLOUKEY

The use of linear perspective is often foregone on account of a convenient lack of means to accomplish it. It is a fact that in a great many cases workmen are not able to grasp the meaning of plans, elevations and sections, but once shown even a rough perspective sketch and the whole thing breaks upon them at once. But few people can make good offhand perspective drawings even when they thoroughly understand the art, and the device shown in the figure is for the purpose of making easy the drawing of simple objects in the perspective.

In the first place the board should be considerably wider than the required drawing, so that the vanishing points may be located far enough away to look well. The two straight edges are made

by gluing a little piece on the straight side at one end so that the hole can be made in line with the edge to be used. Brads are driven into the board at the vanishing points as shown, and a straight edge dropped over each one. Now with a vertical line to begin with, the four sides of the plan can be laid off without taking the rulers off of the pins. Indeed it is not intended to take them off at all until the drawing is completed. When using the T square or triangle the rulers may be flipped over out of the way and still be right at hand when needed, without the draftsman stopping to see that they are in the right place.

It is astonishing how quickly one can do an accurate perspective by the use of these straight-edges, and as it takes but a few minutes' time to rig up a set, no shop or drafting room should be without a set of them.

ADVANTAGES OF PLASTERED HOUSES

"What is the difference in the price of a plastered house and a shiplapped or ceiled one?" I have been asked this question many times, and for the benefit of those who do not know will say a plastered house is the cheapest.

Why? To begin with, it costs but very little more to plaster a house than to seal or shiplap and paper it. Say about five or six cents on the dollar more. Of course, this makes some difference to begin with, but the difference in insurance will offset this in a few years, and then in a shiplapped house that has been canvased and papered, which has to be done at least once a year, you are often annoyed by seeing the paper leave the wall in places—coming off when you are looking for company the next day, and in wet weather it will wrinkle all over the house and straighten out in dry weather. This does not occur in plastered houses.

Then again, any doctor will tell you that your health is safer in a plastered house than in one that is not.

Any fuel dealer will tell you that your coal bill will be cut in half in a plastered house. Your wife wil say: "Oh! Dear! It is so much more pleasant to live in a plastered house in the summer. I find it much cooler than the old hull we just moved out of."

Even the cook will notice the difference in living in a plastered house. There are no mice to be cutting holes in the flour bag—the rats have no place to hide, and she can't find any cockroaches to put in the pudding.—Exchange.

SOME HINTS ON BRICK CHIMNEY BUILDING WITH DEFINITIONS OF SOME TERMS

CHIMNEY STACKS.

Enclosed channels, formed usually in brick work, to discharge (1) smoke, are termed smoke flues; (2) vitiated atmosphere, are termed foul air flues; a construction containing one or more vertical flues being known as a chimney stack.

THEORY.

Air, upon being heated, ascends; its velocity being determined by the well-known kinematical formula $V^2 = 2gh$, and if the value of g be taken as 32, $V = 8\sqrt{h}$, and $h = Ht \times .002$, where H equals the height of column or heated air in feet, and t the excess in degrees Fahr., of the column of heated air over the temperature of the external air.

SMOKY FLUES.

Theory points out that an increased velocity may be obtained by increasing the height or raising the temperature, and the greater

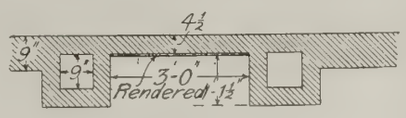


FIG. 1.

the upward velocity the less will be the probability of a down draught, the latter causing what is known as a smoky chimney, and it suggests that a flue with a small volume of air to rarify, with a comparatively great height, is more effective than an equal volume in a flue with a less height.

PREVENTION OF DOWN DRAUGHTS.

To prevent down draught no external chimney opening for the discharging of smoke should have a lower level than any other similar flue exit in close proximity, and it is in addition preferable for this opening to be about 3 feet above any adjacent ridges or walls.

Care taken in this matter would to a large extent render un-

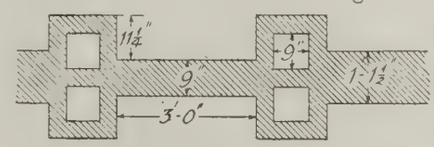

FIG. 2.

necessary cowls and other expedients for the so-called "cure for smoky chimneys."

FLUES.

The flues should be built with at least one bend with an internal angle of not less than 130 degrees. They must be gradual and easy, so as to offer a minimum resistance to the up current. Gusts of wind and down draughts are retarded by the bends in the flues; the same sectional area should be kept throughout till near the exit, when a small contraction in area is conducive to an increased velocity.

CLASSIFICATION OF SMOKE FLUES.

The plans of chimneys may be arranged in three ways, viz.: (*a*) back to back, as shown in Fig. 2; (*b*) side by side, or interlacing; (*c*) diagonally.

Figure 1 shows the first method, with 9 in. x 9 in. flues, with the backs made 4½ inches in thickness, when, to comply with some city by-laws, they must be rendered. This arrangement is mostly adopted to curtail expense.

Figures 5 and 6, the usual arrangement of fireplaces and flues in the external walls of houses.

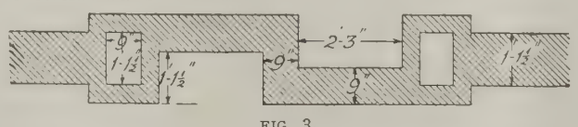

FIG. 3.

Figures 7 and 8 show an elevation and section of a system of flues back to back in a party wall. Figures 9 to 13 show the plan of the courses at each story of this system.

The interlacing system, as shown in figure 3, is sometimes used in order that the projection into the room may be as small as possible; but it could not be adopted in party walls, except where both houses belong to the same property, as the flues would project beyond the center line. The diagonal method, as shown in Fig. 4, is more particularly suitable for use in small rooms, where a fireplace near the center of the room would not be convenient. Angle fireplaces may be arranged with one or in groups of two, three or four at any one level.

GENERALLY.

Every fireplace should have a separate flue, and in a stack the partition walls or withes must be smoke-proof. Any connection between flues causes smoky chimneys.

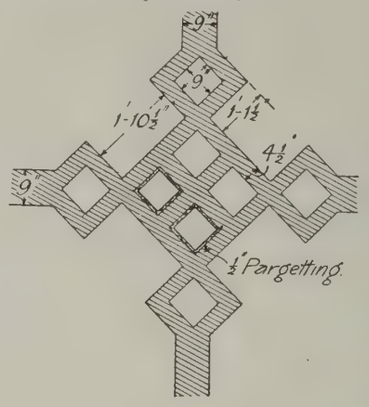

FIG. 4.

A grouping of flues in a building tends to economy and effectiveness.

The outer brickwork surrounding flues, to act effectively as a screen from the outer air, and as an efficient non-conductor of heat, is best when not less than 9 inches in thickness. The withes are

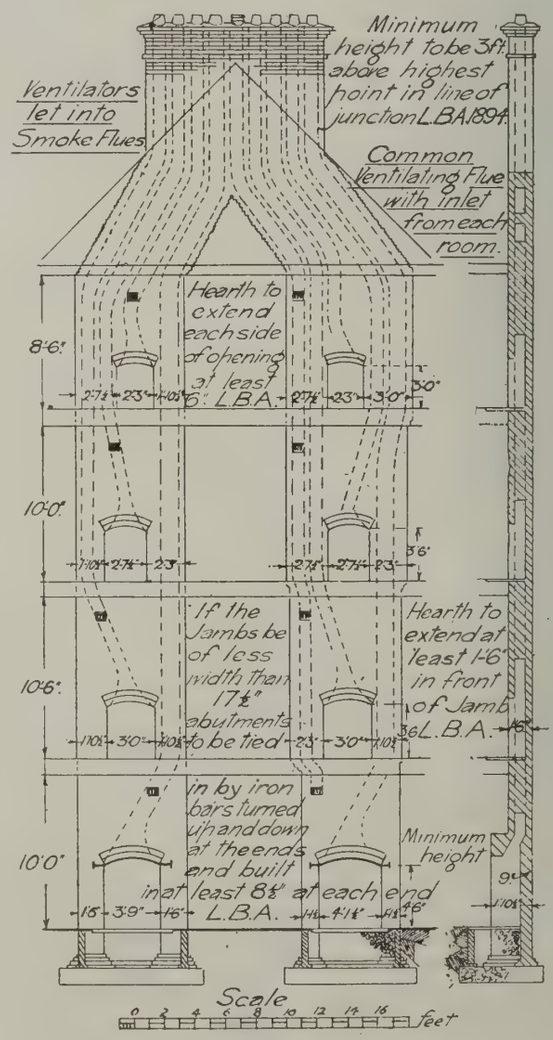

FIG. 5. FIG. 6.

usually half a brick thick, but great care must be exercised to have a thorough bond at the gathering over of the withes.

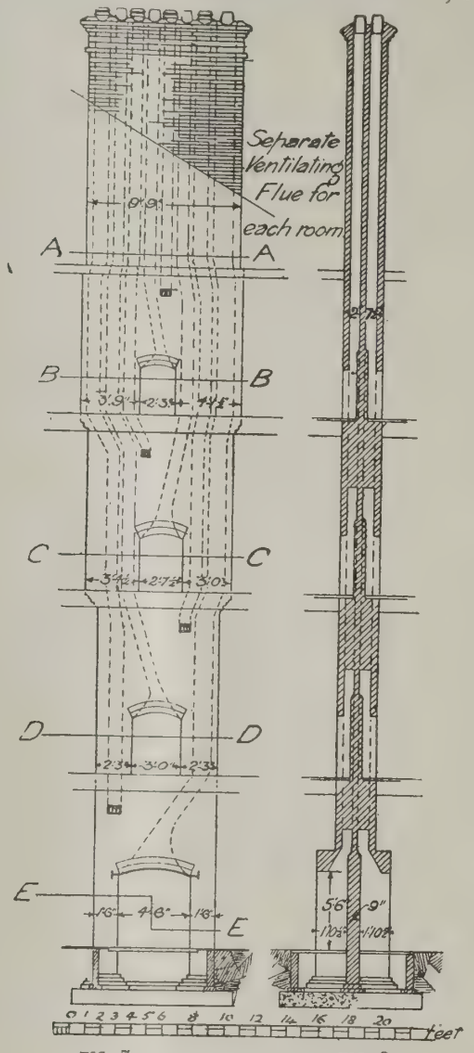
CHIMNEY BOND.

The bonding in chimneys with 4½ inch backs is most effectively accomplished by the use of Flemish bond; this method lends itself to the bricks of the withes of one course forming the face

headers, and bats only being used on face in the alternate courses. The use of English bond for 4½ inch backs necessitates a considerable amount of cutting, thus causing the work to be weak and expensive.

MATERIAL FOR FLUES.

The materials used for chimneys must be incombustible, durable, and sufficiently stable to resist external forces, such as wind



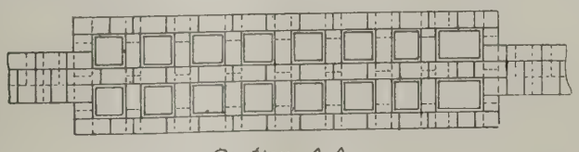


FIG. 7. FIG. 8.

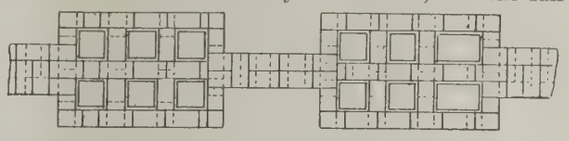
pressure. Without the assistance of ties or any other special construction, brick-work best satisfies these conditions.

DIMENSIONS OF FLUES.

Flues might very well be made 9 inches square; but the use of 14 in. x 9 in., or circular 12 inches diameter is enforced in some cities. There is but little doubt, however, that the use of a flue 9 inches square would very often prevent smoky chimneys, as on account of the smaller sectional area, a greater draught is created. Of late years 9 in. x 9 in. flues have been generally used as the



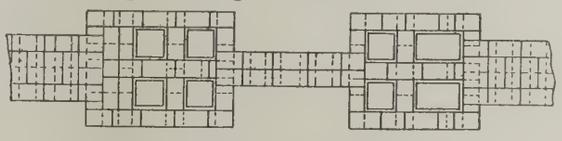
Section A.A

FIG. 9.

standard dimensions for flues for ordinary purposes, 9 in. x 9 in. rectangular and 10 inch circular fire-clay flues are largely used instead of the pargetted lining. These make a clean lining, and the liability of the withes becoming imperfect is very much reduced.

FOUNDATIONS FOR CHIMNEYS.

Some by-laws provide that all chimneys must be built upon solid foundations with footings similar to those of the wall in which the chimney is built, or upon sufficient corbels of bricks or stone, or other incombustible substances, as in the case of a chimney commencing above a shop. This corbelling must not project more than the thickness of the walls below the corbel. The corbelling must be done properly, otherwise the center of gravity of the mass will be brought dangerously near the face of the lower part of the wall, and there will be a tendency to overturn, and the fall of the



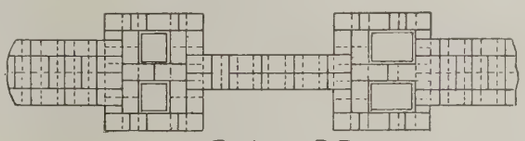
Section B.B

FIG. 10.

walls inwards at times suggests this as one reason among others for the direction of the fall.

PARGETTING.

All flues should be pargetted as they are carried up, unless lined with a fire-clay lining 1 inch thick, or the spandrel angles filled in with brick work, or other incombustible material. The back or outside of all flues must be rendered, if it be less than 9 in. thick, unless it forms part of the face of an external wall. Pargetting is a rendering on the inside of the flue with ordinary lime water. This is to provide against the accumulation of soot in the joints, or of fire penetrating them. The outside of flue breasts



Section C C

FIG. 11.

should always be rendered, especially behind skirtings and beneath floors, where it is more necessary than elsewhere, owing to the close proximity of woodwork.

THICKNESS OF BACKS OF CHIMNEYS.

Every flue of a furnace, steam boiler, or close fire used for trade purposes, or of any cooking apparatus or range of an hotel, tavern or eating-house, must be surrounded with brickwork not less than 9 inches thick for 10 ft. above the floor level. The back of a chimney opening in a party wall used for a kitchen range must be 9 in. thick for 6 ft. above the chimney opening, and such thickness

Section D D.

FIG. 12.

must be continued at the back of the flue; the backs of all other chimneys from the hearth up to a height of 12 inches above the opening must be at least 4½ inches thick if in an external wall, and 9 inches thick elsewhere than in an external wall.

SUPPORT OF CHIMNEY BREASTS ABOVE OPENINGS.

A sufficient arch of brick or stone, or a bar of iron, must be built over the opening of every chimney, and, if the breast project more than 4½ inches and the jambs be less than 13½ inches, the abutments must be tied in with a wrought-iron chimney bar 18 inches longer than the opening. In most cases the breasts project 9 inches or more, and, therefore, if the jambs are less than 13½ inches, these chimney bars must be used, one for each brick in the horizontal thickness of the arch. The ends of chimney-bars should be caulked, i. e., cut and turned up and down.

WIDTH OF JAMBS.

Most by-laws require that the jambs must be at least 9 in. wide on each side of chimney opening, and the brick work surrounding any flue not less than 4½ inches thick.

THICKNESS OF BRICK WORK ON UPPER SIDE OF FLUES.

All chimneys must be carried up 4½ inches least thickness to a height of not less than 3 feet above the highest point in the line of junction with the adjoining roof, flat, or gutter. It is, however, generally advisable to carry the chimney 3 feet above the ridge-line to prevent down draught.

If any interior angle in a flue be less than 130 degrees, a soot door must be provided for cleaning. This is usually specified as 6 inches soot door and frame.

No pipe used for conveying smoke or the products of combustion may be fixed at a distance less than 9 inches from any woodwork.

A BUILDER'S COURSE IN ARCHITECTURAL DRAWING.

RALPH F. WINDOES.

PLATE XVI.—PRELIMINARY SKETCHING.

An architectural draftsman is often called upon to make a sketch of the room arrangement of a building before he is ordered to proceed with the working drawings. He is given the data and it is advised that he make a number of sketches before submitting ones. He should study each sketch separately and decide upon the best arrangement. Or he may be given a sketch made by another, the architect or his client, and given instructions to get out a set of preliminary drawings or even the working drawings themselves from them. In any event he must be capable of producing and reading a good freehand sketch, so we shall take it up in Plate XVI.

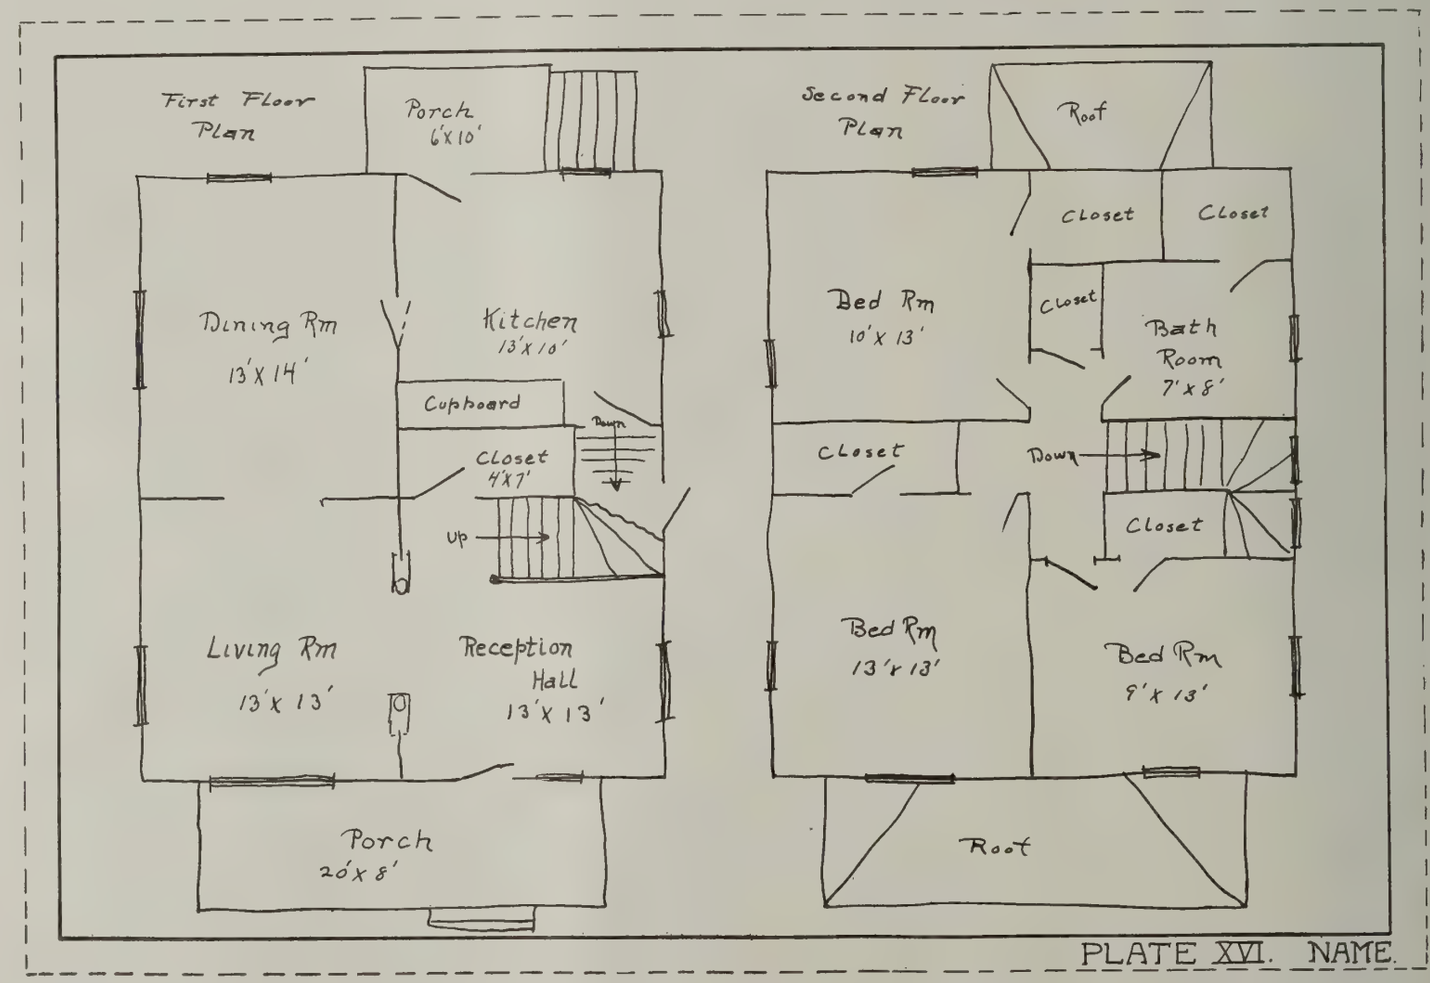


PLATE XVI. NAME.

Here the requirements were to sketch a medium sized frame dwelling containing a reception hall, living room, dining room, kitchen, three bedrooms, bathroom and sufficient closet space. The entire building should occupy ground space of about 26 ft. by 45 ft. Perhaps there was more data included but this is sufficient for a good draftsman to work upon.

He begins his labors by spreading a piece of tracing paper over a sheet of co-ordinate paper so that the lines will serve as a guide for his lines and each little square serve as a unit for his dimensions, as a foot. If he has no co-ordinate paper he can make some by ruling a number of lines horizontally and vertically on a piece of drawing paper about ¼ in. apart. Next he figures on his given dimensions. He knows that the 26 ft. represents the width and the 45 ft. the length, so he has to take porch and step space from the 45 ft. This leaves him about 26 ft. by 27 ft., nearly a square. This he draws on the paper with a single line, representing his outside walls. Now he figures that he has four rooms to get in on the ground floor, so he draws a line through the center each way, dividing it roughly into four squares. Next comes his stairways. They must run from the reception hall and kitchen so he knows that these rooms must be on the same side of the house. Then he plans his stairs. The main stairs will take up less room by running up half a flight and then continuing in a parallel line on the opposite side of the wall. This gives room for the cellar stairs under and allows for a platform there for a grade door. And not only that but he knows that two closets can be worked in with this kind of a stair. He starts in the reception hall with an open staircase and goes up nearly half the flight which he breaks off with a broken line. Then he plans his first floor closet which must be under the last part of the flight. The width and the length of this is governed by the width of the stairs. This gives him the location of the cellar stairs which terminate in the first floor plan with the broken line. Next he plans his cupboard, doors and windows, porches and puts in the lettering and dimensions.

Now he is ready for the second floor sketch. Of course, the outside wall line remains the same so he puts that in the same in size as the first floor. Now he has three bedrooms, a bath room and closets to plan; and he must not forget his staircase, so he puts that in first, carrying it around from where he left it off on the first floor plan. He knows that it is a good plan to have his second floor partitions come directly over the first floor if possible,

so he puts them in roughly and only erases them where he has to for his hall space. Then he starts in the corner over the living room and makes this bedroom the same size. Next he puts in a closet and makes it the same width as his staircase. He cuts it off to allow a doorway from this first bedroom into the hall. His other bedroom on the front is already provided with closet space so he puts it in and his hall door. Notice that he does not put this door out even with the door of the large bedroom as this would bring it directly at the head of the stairs, which is a great disadvantage. Then he allows more hall space at the other side of the stairs, which gives him room for doors into the third bedroom and into the bath. The bath does not need to be very large so he cuts off the back end of it and provides closets for it and the third bedroom. He is very economical and does not care to waste any space so he cuts off the back end of the hall with a partition and a door and provides another closet, also a scuttle entrance into the attic. With the addition of the windows, doors, roofs, lettering and dimensioning, his second floor sketch is complete.

Perhaps he is not satisfied entirely with this plan, so he makes two or three more with different arrangements, and, considering them all, finally returns to this one as the best. He has certainly lived up to the requirements of the case, provided closets for each bedroom and the bath, an extra closet upstairs, and a closet downstairs off from the reception hall where it is most needed.

This is a typical example and a very easy one to plan so it is advisable that the student do not copy this but to work up a problem of his own and try to solve it in all the phases here presented.

PLATE XVII.—CONVENTIONAL DRAWING.

After the sketches given on Plate XVI were approved by the architect and his client, the draftsman was instructed to prepare a set of conventional drawings of the house, drawn to scale and lettered. The result is shown on Plate XVII. His scale was 3/16 inch to the foot, and all of the drawing was done with a rather soft pencil, about a 4 H. He placed his paper upon the board and drew all of the lines with T-square and triangles in order to give the drawing as neat an appearance as possible. He left out a number of details and improved, architecturally, on the arrangement in the sketches. He drew all of his walls with a double line, representing six inches, and went over them with a pencil excepting where the windows and the doors came. He lengthened the rear porch and put railings on both porches. The front porch roof he also improved upon by allowing for a gable which threw the water away from the steps. He planned his stairways more accurately, allowed for a chimney which could carry the smoke from the furnace and the kitchen range and changed the size of some of the rooms.

When these have been approved the draftsman is instructed to get the working drawings out from them, so the more accurately these are made, the easier will be his task when the working drawings are drawn.

The student should make a close study of this plate and should attempt to make such plans from the best sketch that he completed.

(To be Continued.)

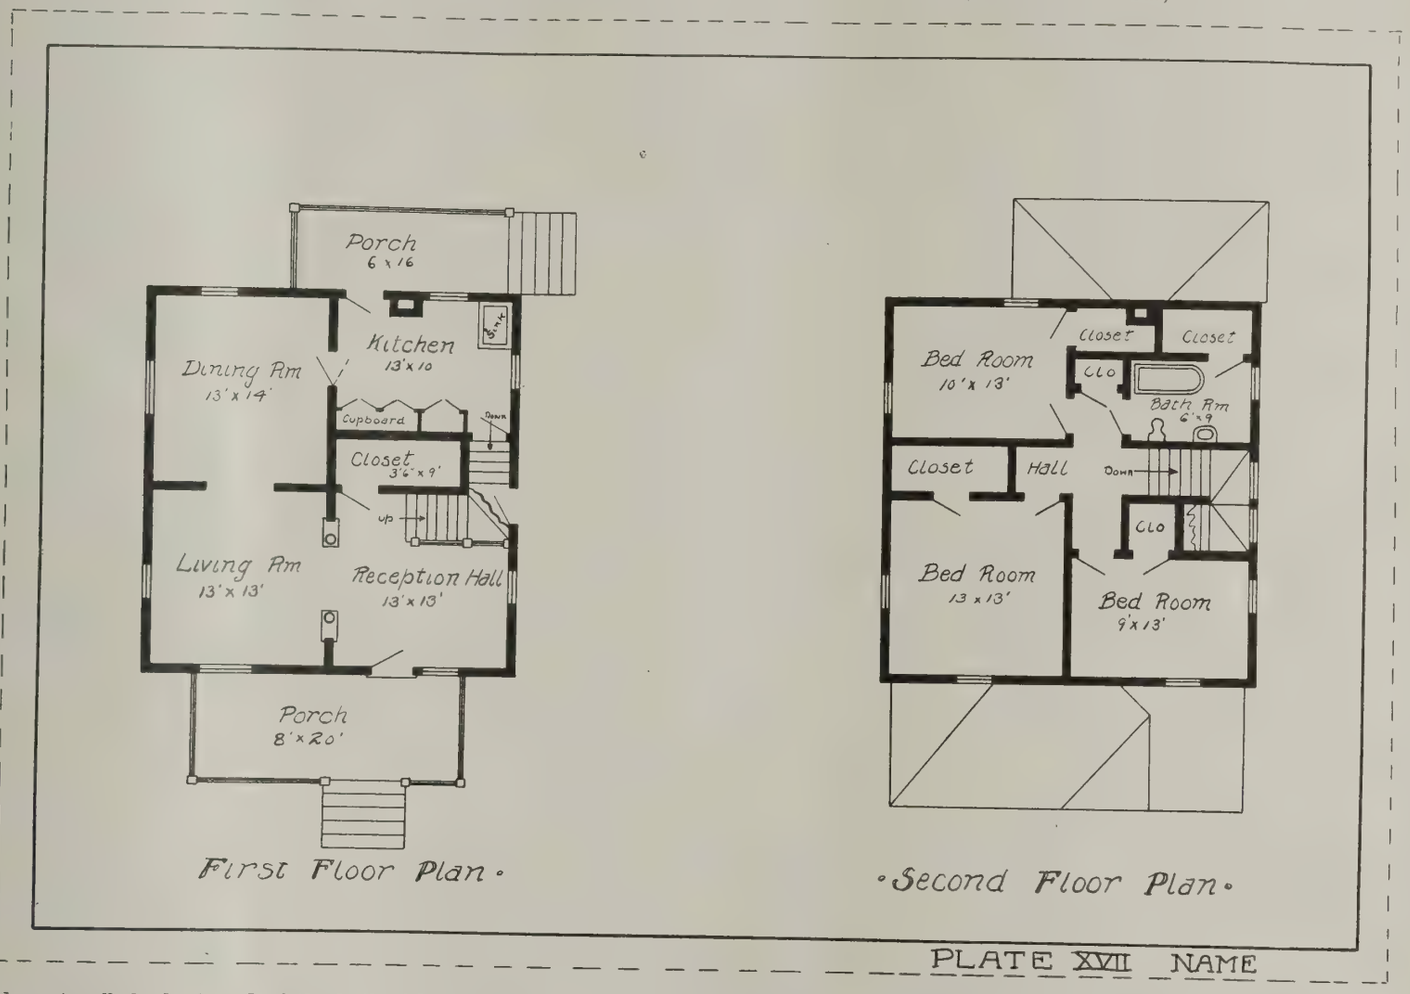

PLATE XVII NAME

DRYING OUT NEW BUILDINGS

Hitherto occupation of newly built houses has been delayed in order to allow them to dry, but with the use of this new apparatus freshly plastered rooms can be perfectly dried within three days, and the excessive moisture of the walls completely extracted.

The apparatus consists of a stove with a fire box, suitable for coke fuel, surrounded by a number of small-diameter tubes, similar to gas pipes. By means of the apparatus fresh, dry outside air enters constantly into the air-supply tubes, and is highly heated in the tubes surrounding the fireplace. It ascends in a dry-heated state in the room, passes along the ceiling and walls, and absorbs the dampness, sinking down after being saturated with the same and re-entering the apparatus. It then mixes with the coke gases in the outlet tube for the smoke, and eventually escapes into the chimney.

This constantly renewed fresh outside air furnishes an abundance of carbonic acid to the mortar, thus hardening it, and producing in a short time the same effect as if the mortar had dried naturally. It is claimed by this system that no moisture can possibly show later on.

A striking recommendation for the apparatus is that the German law prohibiting the habitation of any house until six months after construction is abrogated by the authorities where this system is used.

OUR READERS' PAGES

[The Editor does not hold himself responsible for the opinion of correspondents. Short, crisp letters will be appreciated. To insure publication, the name and address of the writer must accompany the communication, not necessarily for publication. Sketches of work or methods will receive our earnest attention. These columns are open to our readers at all times without charge, and any questions or experiences will be given proper space.—Editor.]

ANSWERS

RAISING A FRAME BUILDING.

From "Old Builder," Syracuse, N. Y.

In answer to J. B. Golden, B. C.

See that there is a good sill all around before starting to raise. Place six or seven heavy timbers clear across building, bolting two together, if you cannot get them 36 ft. long. Under each end of these place a large jackscrew. Raise only a few inches at a time, keeping the sill level by giving each screw one or two turns at a time, or else turn them all an equal distance at a given signal. Provide plenty of cribbing—6x6x4 feet is a good size, and keep blocked up all the time so there will be no chance for the building to fall. Every night let the screws down a little so the building rests firmly on the cribbing. If a wall is to be built under the building, you can build up piers between the jacks. Remember to take short lifts on the jacks and keep sill level and blocked up. Never lift on one jack while others are loose. Raising buildings is such a particular job that in the large cities a license is required before one is allowed to start.

From "Joe B.," Winnipeg, Man.

Answering "J. B." of Golden, B. C.

The proper way to raise a frame building, or any other building for that matter, is by using screw-jacks under foundation. If the building is a heavy frame, well put together, it might be raised by using heavy levers, lifting one end of the building a little, then blocking it up, and using the levers at the other end, and lifting each end, a little at a time, and blocking up, until the right height is attained. This is a clumsy way and should not be used if the frame is scantling or balloon built. There is nothing like the screw-jack for raising a building.

SELECTING HAND SAWS.

From an "Old Hand," Trenton, N. J.

In answer to "Boy Apprentice" of Kansas City, if he has no particular love for any make of saws, it would be well for him to consult some of the men in his own shop, as they could give him some "pointers." It would be impossible for me to write out at length and they might loan him their saws so he could try them for himself and note their good qualities. I am now over twenty-five years in the business of woodworking and during that time I have worked with many different kinds of saws, English and American, and while I have found differences, I have noticed that the "differences" did not amount to much, only in exceptional cases, and in the advertisements. Sometimes you will get a poor saw, one that has passed the keen eyes of the man appointed by the makers to see no defective saws leave the factory. This may occur with any manufacturer of saws, but to their credit it may be said that any one of our American saw makers will gladly send another saw to replace the defective one—free of charge—or return the money paid, if the matter is brought to their notice. While I don't pretend to say that any one make of saws is better all round than any other make, there are certain differences which suit one class of men which another class of men will not tolerate for a minute, if they can avoid them. My own experience has been about as follows: My first set of saws consisted of a cut-off, a rip-saw, a panel, or siding saw, as we called it, and a back saw with a brass back, and which, by the way, I still have. The rip and the panel saw were American made, the cut-off and back saw were English, the one a Sorby, the back saw from Sheffield, name undistinguishable. All of these saws served me well and for many years I used no others. Fifteen years ago I lost my tools, with a few exceptions, by fire. I then supplied myself with a complete outfit of saws made by Disston & Sons of Philadelphia. They cut well and clean, but somehow I did not like them at first. They seemed to tire me out quicker than the old saws. In less than six months, however, when I got accustomed to the set of the handles and hang of the blades I got to like them, and I found they held their edge longer and required to be filed less often than the old saws I lost. One day I had an opportunity to dispose of my whole "kit" and handsome tool chest for a good price, to a man who was going to Honolulu on a short call and big pay. I let them go and set to work to buy a new outfit. Having two boys of my own, old enough to help me, I began contracting and procured enough tools to go all round, and this time I bought without reference to names of makers, using my own judgment in selecting. This time I bought twelve saws—3 Disstons, 5 Atkins Silver Steel, 3 Simonds, different styles, and one Greyhound saw made by Geo. H. Bishop & Co. Afterwards, I bought several other saws for the use of my boys and hired workmen. The workmen and my boys fell dead in love with the Greyhound, and I had to buy three more cross-cuts because of their quick-cutting qualities. Simonds saws are doing good service and seem to be made for use, not for ornament. The old Disston saws still hold up their end of the work all right, and are the ones I make the boys take out with them when they have work outside the "shop." The Silver Steel saws, however, seem to be the favorites with all my workmen, as they consider them easier to work. They do not tire the arm and they cut freely and seem less likely to buckle than most of the others. The boys claim for them, "lightness, quick cutting, easily kept from rusting and perfect hanging." "Boy Apprentice" will see from this "Actual Experience" that there is little choice to be made from the four makers of saws, but my own boys say to me, "Tell him, 'Dad,' to buy Atkins Silver Steel saws. We are sure he will like them best, because they cut so easily and always look nice." So there you are!

From "Tabbot," Dayton, Ohio.

"Boy Apprentice" ought to know, without telling, the kind and style of hand saws he should buy for his own use, if he uses saws at all. I don't think it makes much difference as to the manufacturer's name on the blade, so far as to the cutting qualities. As I take it, this depends more on the filer than on the maker. If he he is a good filer, he can make any old "brier" edged thing cut well for a while, but a poor filer will ruin the reputation of the best saw ever made, in two filings. Learn to be a good filer, or get your saws filed by a professional filer, and most any one of the saws made by an American firm will give good satisfaction. For myself, I scarcely think of the maker when I buy. I judge the saw on its merits. If it is hung to suit my hand, has the right number of teeth per inch, the proper ring and is elastic and not too heavy on the point, firm in the handle, well riveted, and stiff enough to be worked without buckling, I don't hesitate about buying. If "Boy Apprentice" will use his brains, mixed with a little judgment, when he buys his saws, he will likely get the best, for him, the market affords. Perhaps it would not be a bad idea for him to read over the various saw catalogues and saw advertisements. He will get some pointers from them, also some very useful knowledge.

From J. B., Lead, S. Dak.:

Boy apprentice wants to know what kind and make of hand saws are the best. It seems to me that an apprentice who has almost served his time ought to know the kind necessary for the different work he is to perform. A carpenter usually has a 28-inch rip saw, say 5 or 6 points to the inch, a 26-inch cut off saw, say 7 or 8 points, also a 26-inch cut off saw 10 or 11 points to the inch, a 20-inch siding saw 10 or 11 points to the inch. I would advise Henry Disston & Son. The first two cast steel and the others spring steel. This advice is from one who has had 40 years' experience.

SOUND PROOFING.

From "Rambler," Scranton, Pa.

Answering H. M. H., Leadmine, Wis.

The principle on which sound proofing is used is that a continuous layer must entirely cover the space from which the sound comes. In the case of a large room, the floor should be covered with a deadening felt, and on top of this 1x2 strips laid which are not fastened to the under floor. On these strips is nailed the top flooring, care being taken that no nails extend through the nail strips and into the floor below, as that would carry sound through the floor proofing. This, of course, requires that the finished floor is raised about two inches, and may necessitate sawing off the doors or making other provisions for taking care of them. There are several forms of deadening felt on the market and advertised in THE NATIONAL BUILDER, and any of them will be glad to send you further information.

From J. B. Lead., So. Dak.:

Replying to H. H. H., Leadmine, Wis., to deaden the floor of the lodge room on second floor, take up all the platforms, if any, and the base around the wall; then strip the present floor with 2-inch by 2-inch over every joist. Then spread lime mortar on the floor between the strips, about ¾ to 1 inch deep. Lay a floor on top of these strips and put back the platforms and base, and you will have a sound proof floor.

STRENGTH OF WOOD BEAMS.

The formula for finding the safe loads on wood beams are derived from the:

Width of beam in inches = b
Depth of beam in inches = d
Span of beam in feet = S

and a constant "A" which is the safe load for a piece of the material one inch square on a span of one foot.

For different woods "A" varies as shown in the following table:

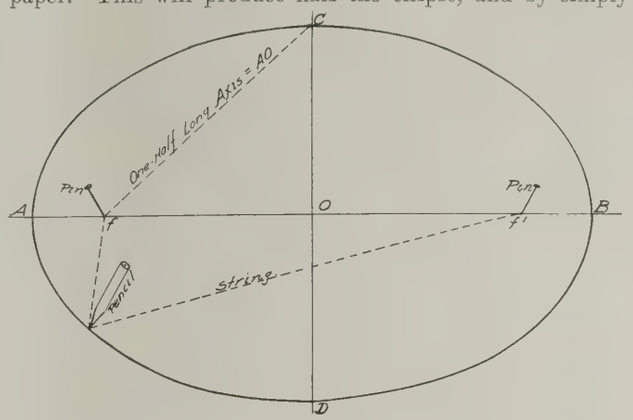
Value of constant "A" for various woods.

Chestnut	60	Eastern White Pine	60
Hemlock	55	Western White Pine	65
White Oak	75	Texas Yellow Pine	90
Georgia Yellow Pine	100	Spruce	70
Oregon Yellow Pine	90	Poplar or Whitewood	65
Red or Norway Pine	70	California Redwood	60

To find the safe load for a given beam substitute the values in the formula:

$$\text{Safe Loads} = \frac{2\ b\ d^2\ A}{S}$$

Thus for a 6x8 Georgia Yellow Pine with 10-foot span we would have $\frac{2\times6\times64\times100}{10} = 7680$ lbs.



This is on the supposition that the load is evenly distributed over the entire length of the beam. For a concentrated load at the center take one-half this result, or use the formula:

$$\text{Safe Load} = \frac{b\ d^2\ A}{S}$$

For concentrated loads not on the center, the value is between these limits, being more than a central contentrated load, and less than evenly distributed load. The nearer the concentrated load approaches the support the greater it can be.

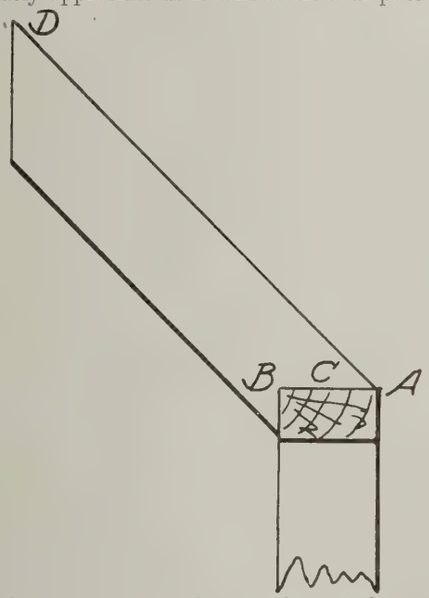
DRAWING AN ELLIPSE.

From "Angles and Curves," Santa Ana, Cal., in reply to J. E. I., Shenandoah, Iowa: The simplest, yet most accurate way, to draw an ellipse is by aid of two pins, a piece of firm string, and a pair of compasses; lay off the long axis AB, then the short axis, bisecting the long in the center, and exactly at right angles to the long axis; set the compass points as far apart as one-half the long axis measures, then with the compass so set, using one extreme of the short axis for a center, trace an arc across the long axis; the point where this arc crosses the long axis will be the location of one focus and the other focus can be located in the same manner. Set a pin firmly at each focus and tie an end of the string to one of these pins, then wrap the other end of the string around the other pin once or twice, drawing it in just far enough to that when stretched by the pencil, the pencil point will just reach the extreme of the short axis. Hold the loose end of the string down firmly with the finger, and trace a line according to the way the string guides the pencil, taking care to keep the string down on the paper. This will produce half the ellipse, and by simply re-

versing the string, the other half may be easily drawn in the same method. This method produces a true ellipse, whereas compasses alone cannot, because no part of an ellipse is any part of a circle. By using a wire in place of the string, I have drawn ellipses measuring more than ten feet in diameter.

QUESTIONS

PURLINE POSTS.



From D. S. S., Elwood, Oreg.:

Will some reader of the NATIONAL BUILDER give me the best and most practical method of finding the length of purline posts, without the use of diagrams?

RAFTER NAMES.

From L. M. H., San Jose, Calif.:

Will you kindly answer the following question which I assure you I will greatly appreciate as it will settle a dispute among some "chips" here.

What is the proper name for a rafter at the point where it comes in contact with the upper outside corner of the plate. Some call it the "heel" others the "toe" which is right or is there a more proper name than either?

REMOVING PAINT.

From A. M. B., St. Louis, Mo.:

I would like to know a way to get a coat of paint off a door without burning or scraping it off.

MAPLE FLOORING.

From M. A. V., St. Ignatius, Mont. I have been working at the carpenters' trade for several years but have never had much maple flooring to lay. Can you give me any pointers on this class of work?

A USEFUL BOOKCASE

By AETNA

For the reception of books, drawing instruments, photographic requisites, and periodicals, which accumulate surprisingly fast, there is nothing better than a large and commodious bookcase, as shown at Figs. 1 and 2. The writer, feeling the need of such accommodation for his numerous paraphernalia, contemplated making up in hard wood the design shown in Fig. 2, with upper and lower carcases to render its removal an easier matter. There is undeniably a great amount of work in the construction of such a bookcase when one has not the aid of machine tools, consequently this design never advanced further than the paper stage, but resolved itself into a less pretentious, but more readily constructed affair, illustrated at Figs. 1 and 3. Practically all the necessary material may be purchased machine finished, from stock sizes, at any builders' timber merchant, which considerably lessens the time and labor to be expended upon its construction. Due regard has been given to its portability, which has been effected in a simple, though perhaps a somewhat unorthodox manner. The cornice, the back and sides, etc., are all detachable by the removal of a number of brass screws; thus no difficulty whatever exists where easy transport is concerned.

The set of cupboard doors are 3 feet 6 inches by 1¼ inches thick, with leaded cathedral glass panels in top and wood panels

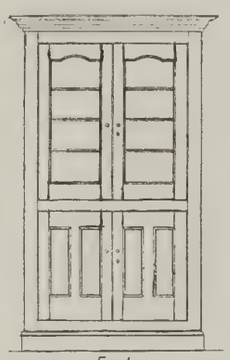


Fig. 1

Fig. 2.

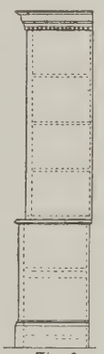

Fig 4.

Fig. 3.

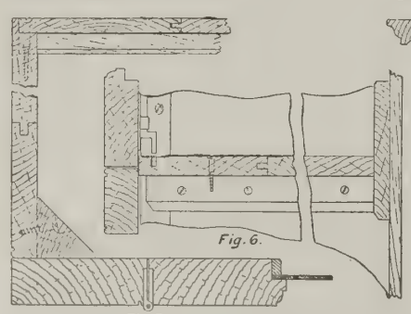

Fig. 6.

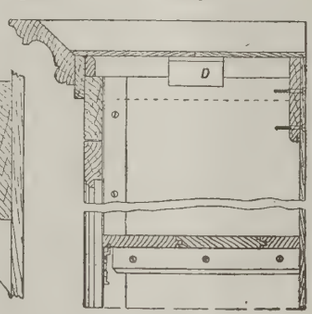
Fig. 5.



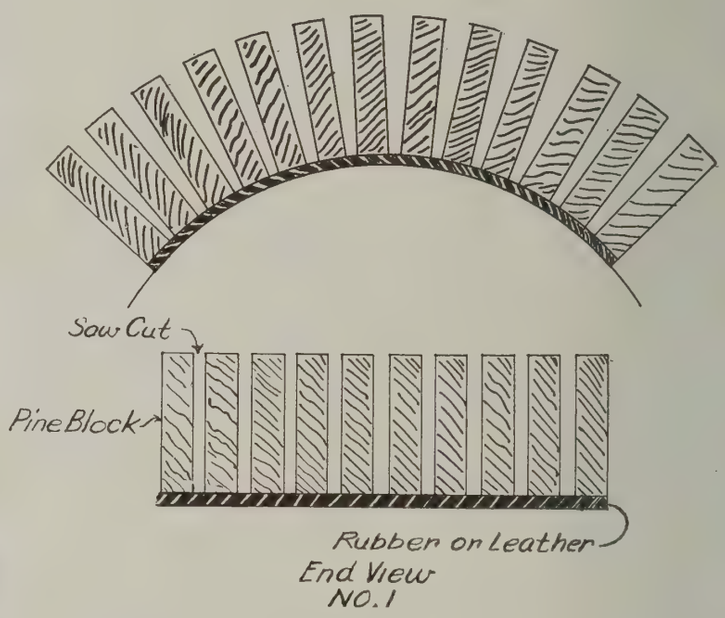


Fig. 7.

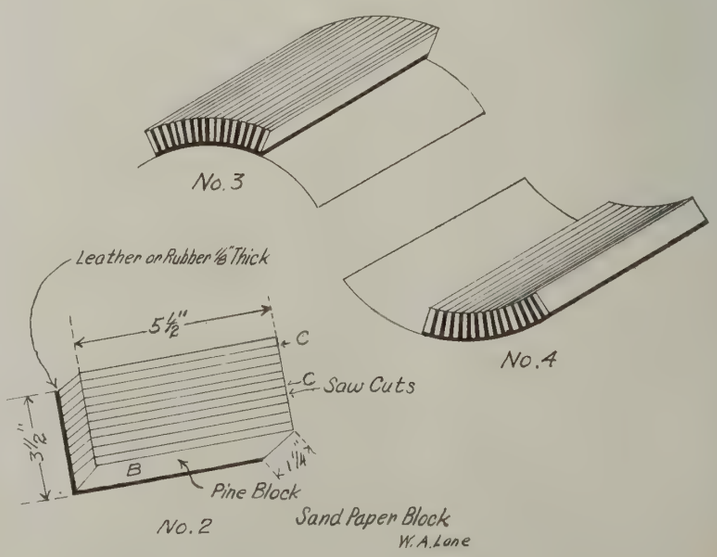


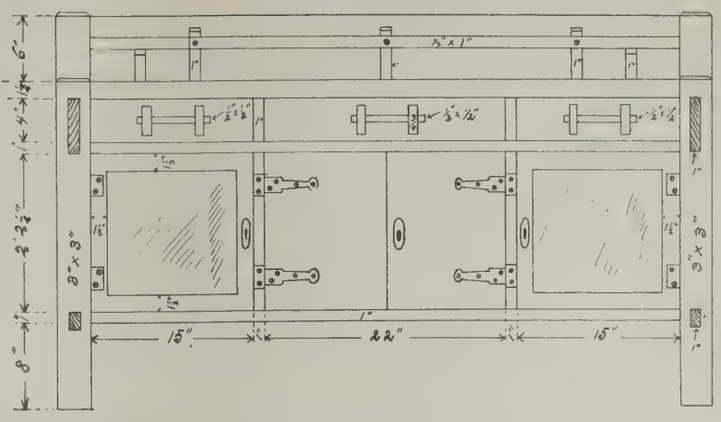
in bottom door; the frame is of the same gauge, 1¼ inches; the stiles being 3¼ inches wide and the top, middle and lower rails respectively 5½ inches, 2½ inches and 7 inches wide. The sides of carcase are made up from 7-inch by ¾-inch square edge, grooved and tongued, jointed boards, planed both sides, glued and clamped till set. In lieu of blocks, a continuous, triangular section fillet is glued and bradded to the inside of front framing, as shown at Fig. 5, to which the sides are attached by means of screws. The back is composed of 7-inch by ½-inch V-jointed, grooved and tongued stuff fixed to three ledges. The back edges of sides are rebated for the ½-inch backing and recessed for a dovetail formed on the ledges. Then screws pass through the whole lot for security. Now battens are screwed on the inner sides to support the shelves, and the second shelf up from the bottom is arrangd to form a stop for th bottom part of glass doors (see Fig. 6). The shelves are 7 inches by ⅞ inch, grooved and tongued boards cut to fit the case nicely. The bottom, middle and top ones are screwed to the battens, thus stiffening the carcase considerably. The top shelf also forms a stop (see Fig. 7), and a pair of small brass blind bolts are fitted which engage in these shelves, and are thereby readily accessible in these positions. The cornice is mitred and fixed to three fillets, which encase the front and sides of the carcase; on the inside of fillets glued blocks are fixed to support the cornice. The front blocks rest on the top rail, while the side blocks at D, Fig. 7, being notched to the top ends of side, prevent any movement of the cornice outwards. The dust boards on top are arranged to come flush with the backing, and also connect the side of cornice, preventing any tendency to springing outwards. The skirting is glued and lightly bradded to the carcase, but is free at the mitres. The doors are hung with 2½-inch brass butts, and furnished with good quality cupboard turns and locks. The whole exterior of carcase should be sand-papered and dusted down, knotted, primed, painted and finished in brush graining, giving a pleasing appearance and harmonizing with its surroundings. —Illustrated Carpenter and Builder.

AN ADJUSTABLE SAND PAPER BLOCK

By W. A. LANE

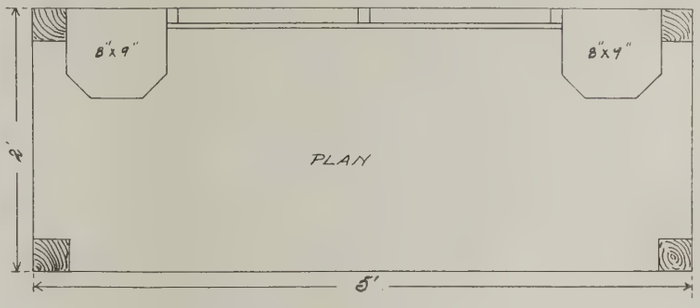
Upon a suitable sized block of wood glue a piece of rubber or leather about ⅛ of an inch thick. When dried well, lay out the saw cuts as shown in drawing No. 1 and No. 2. The saw cuts can be made by hand or on the band saw. Saw through the wooden block to the rubber (or leather); a block 1¼"x3½"x5½" makes a good sized block for either hollow or sound work, and will not cramp the hand—an important item when there is much work to be done.

A MISSION SIDEBOARD



By E. C. LANE

I see no reason why "Mere Man" should do all the furniture designing when it is the woman who uses it most. As for myself, I greatly enjoy planning different pieces of furniture. The sideboard shown is of rather simple design, yet it would meet the requirements of the average family.

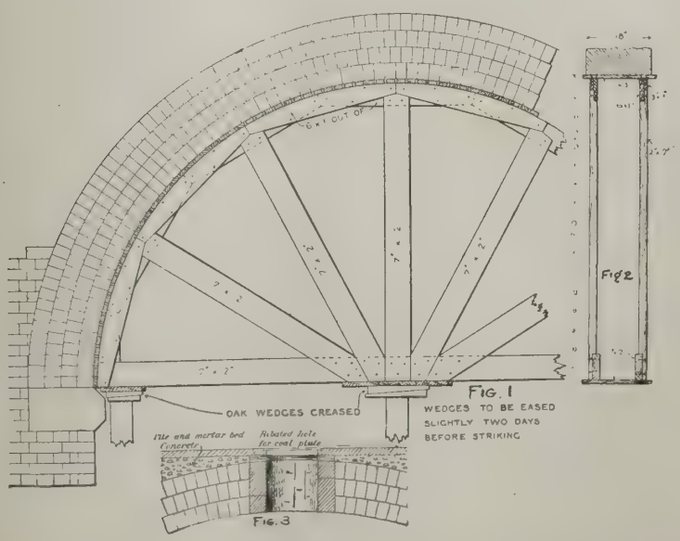


The top provides ample space for odd bits of silver and glass. There is a small rail for one's favorite plates, and at each end a stout little shelf to hold an old Dutch jug, a nut bowl, or any fancied dish. At the center front is a large drawer for the linen in every day use, with a drawer at either side for silver. Below is a deep compartment for extra linen or for china.

At the sides is a roomy receptacle for one's cherished bits of glass, china, copper, etc. Having glass sides as well as doors, one may enjoy the beauty of their best loved possessions at the same time having them shut away from dust and likelihood of being broken. Naturally, this should be of wood to harmonize with the furnishings of the dining room. Some good wood waxed is by far

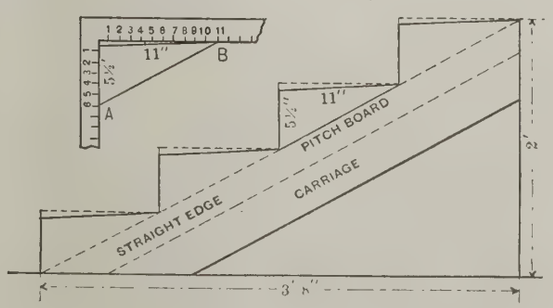
the most artistic and satisfactory. For those who live in Mexico, there is the beautiful genuine mahogany—this would look well with hinges of dull copper. They also have real ebony whose soft blackness needs brass finishings. I strongly advise all to use the wood found in or near their locality. There are numerous woods of beautiful grain and tint lying idle, simply because so many have the idea that only a few well known varieties may be used.

Those who live near forests may explore and no doubt discover many charming specimens, while those fortunate ones who own large estates may utilize what is grown upon their own land.



Think of the joy of having this or other pieces of furniture fashioned from one's own woods, the work on the premises, and if one has the desire and ability, from one's own design. There is surely far more pleasure in the ownership under these circumstances than when one purchases from the shops.

CENTERING AND BRICKWORK

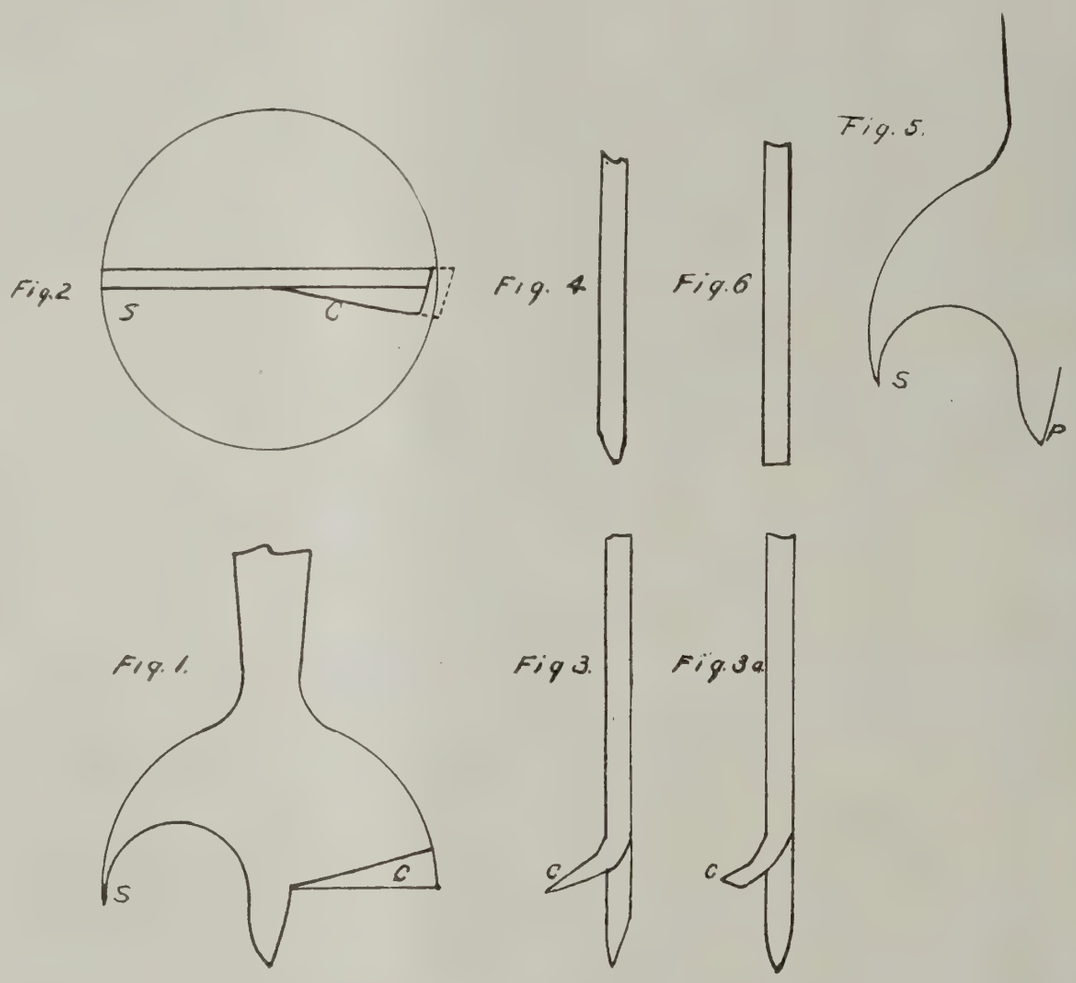


By F. T. H.

SOME time ago a subscriber requested us to send him a sketch showing a method of making a center for a brick arch having four rings, and a radius of fifteen feet. Fig. 1 exhibits a part elevation of the head of an opening of a brick-built structure. It is a semi-circular opening, and as shown, it rests on its centering, all the details of which are given. The springing stones, or imposts, are 21 in. x 12 in. on the face as shown. The manner in which the struts of the centering finish against the ribs is made clear by Fig. 2, which is a vertical section of Fig. 1.

Fig. 3 shows the manner in which a coal hole is formed in an arch having three rings. A circular center is made, being slightly tapered from the top down and is placed vertically with the small end resting on the crown of the center and should be provided with some device for withdrawing when the work is finished. A circular cast iron ring of the right size, and shape, having an iron cover, must finish off at the top of the hole. The cover is movable so that it may be taken off whenever required.

PITCH BOARD FOR STAIR WORK



It will be seen that I cut ¼, ⅜, or ½ inch off the pitch board before laying out the carriages. I always use a straight edge in laying out carriages, a straight edge being spaced off equal to A B, and by keeping the pitch board to the lines on the straight edge, all carriages will be the same.

ADVANTAGES OF THE CENTER-BIT

By L. G.

ALTHOUGH regarded by many as old-fashioned, the center-bit possesses several advantages over the various twist bits which are so popular at present. These advantages appeal perhaps more particularly to the jobbing man than to one who is continually on new work, but even he will sometimes find the center-bit very useful. For instance, in boring a large hole in a hardwood floor, the twist bits generally feed too fast and become hard to turn, as well as acquiring a tendency to run out of plumb. The chief advantages of the center bit are:

1. They are easier to keep in order.
2. They are harder to put out of order.
3. With a certain limit their size may be altered to make either a light or a loose fit for pipe, dowels or anything circular.

To get a center bit into real good working condition several points must be watched closely, and the first is to see that when boring the spur S strike the wood ahead of the cutter C. The spur should not lead by too much, however, as that would throw too great a strain upon it, and possibly break it when going through a hard knot. Care should also be taken that the cutter C does not project (as indicated by dotted lines in Fig. 2) beyond the circle described by the spur when boring, in fact it is just as well to give it plenty of clearance. Now, attend to the spur and see that it has clearance as in Fig. 1 and is not binding, as in Fig. 5. This fault can be cured with a file in a center-bit, but if through running into a nail or any other cause, a twist bit gets this same trouble its days of usefulness are over. The next point and one which is equally important in twist bits is to see that the cutter is leading at its extreme edge, as in Fig. 3, and not binding behind it as at 3a, as although this does not always stop the bit boring at all, it will always make it considerably harder on the man behind the bit.

I have said nothing yet regarding keeping the cutting edges sharp, as that is of course apparent, both as regards the cutter, the spur and the center, but I'd like to point out that the spur will cut much sweeter when sharpened with a round edge as indicated on end view by Fig. 6, and not like Fig. 7, as those sharp corners will scratch rather than cut. The spur should always be sharpened on the inside, so that the trouble indicated in Fig. 5 is not likely to occur. The points that I have here emphasized apply equally, with the exception of the second one, to twist bits, but the principles involved are more easily seen in the center-bit owing to its simpler construction.

The third advantage that I claimed for the center-bit is one which is generally overlooked, but it may be pointed out that by filing the center on the side near the spur so as to increase the distance from the point P to S, it will bore a larger hole, as the spur S will describe a larger circle. Although the increase (or decrease, by filing on the side) thus obtained may appear small, it comes in very useful at times; if, for example, we want to get a fit for a dowel or a pipe and have a bit that comes near the size we want, a touch of the file enables us to bore the hole the exact size required.

REALISM IN ART

A local painter worked three months on a painting. He spent a good deal of money on models, but the finished product justified all his expenditures and all his time. Everybody told him so when his picture was exhibited.

Everybody but one. This lady, whose opinion he valued most, was the one he took to the exhibition with him. "I can hardly wait," she bubbled. "Which is your picture?"

"This one," he told her—and waited.

She studied it in detail.

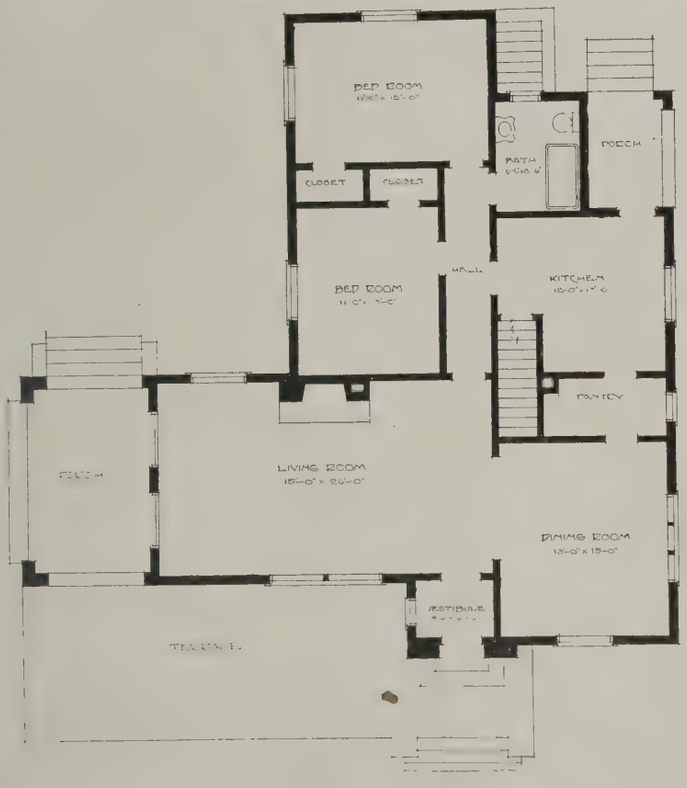
"What is it called?" she wanted to know.

"Wood Nymphs."

"How silly of me to ask! They're so natural. Why, anybody would think they were really made of wood!"—Cleveland Plain Dealer.

THREE CONCRETE BUNGALOWS

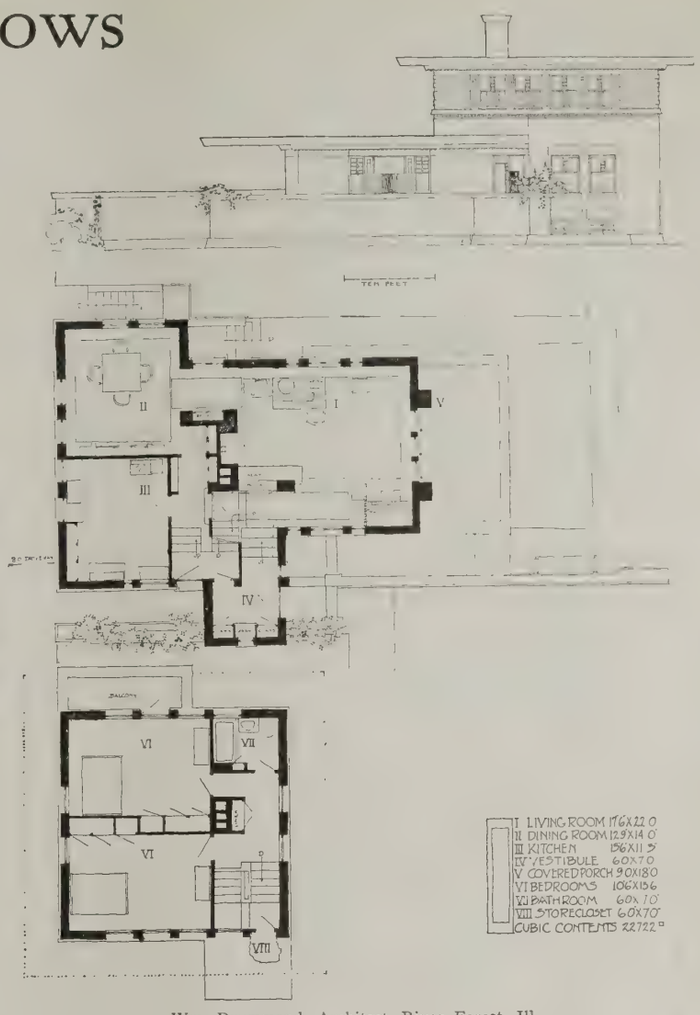
The competition for designing a concrete bungalow recently held by the Cement Products Company brought out a great many designs of unusual excellence.



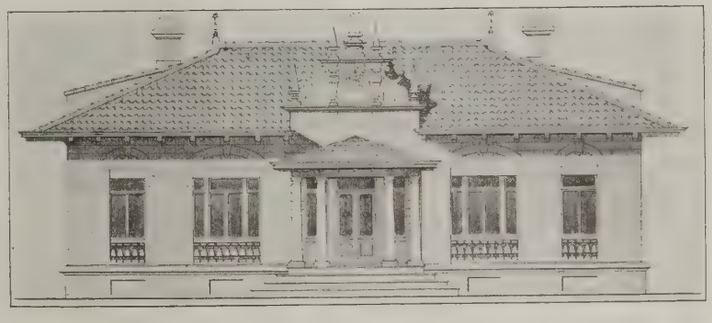
Through the courtesy of the Cement Products Company, we reproduce on this page three of the designs submitted.

In the design by Mr. H. P. Bartlett, we have walls of monolithic construction, with a flat roof. The exterior faces of outside walls are to be treated with acid to expose the aggregate.

Mr. Wm. Drummond secured favorable mention for his two story design, showing a delightful arrangement of the lot as well as the interior.

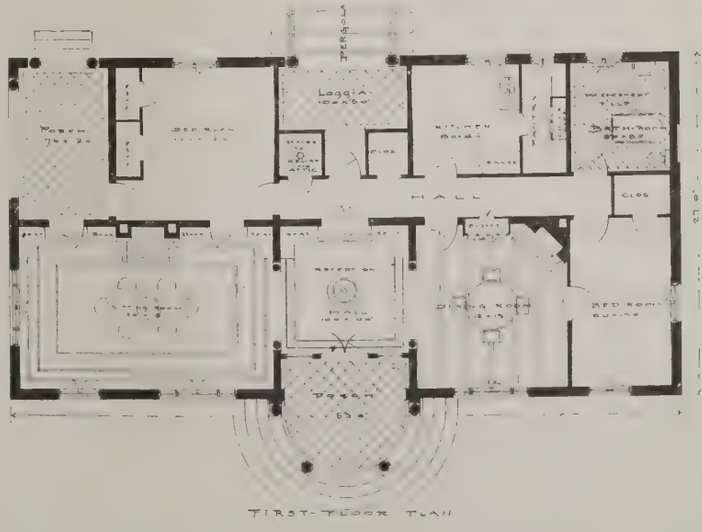


H. P. Bartlett, Architect, Indianapolis.

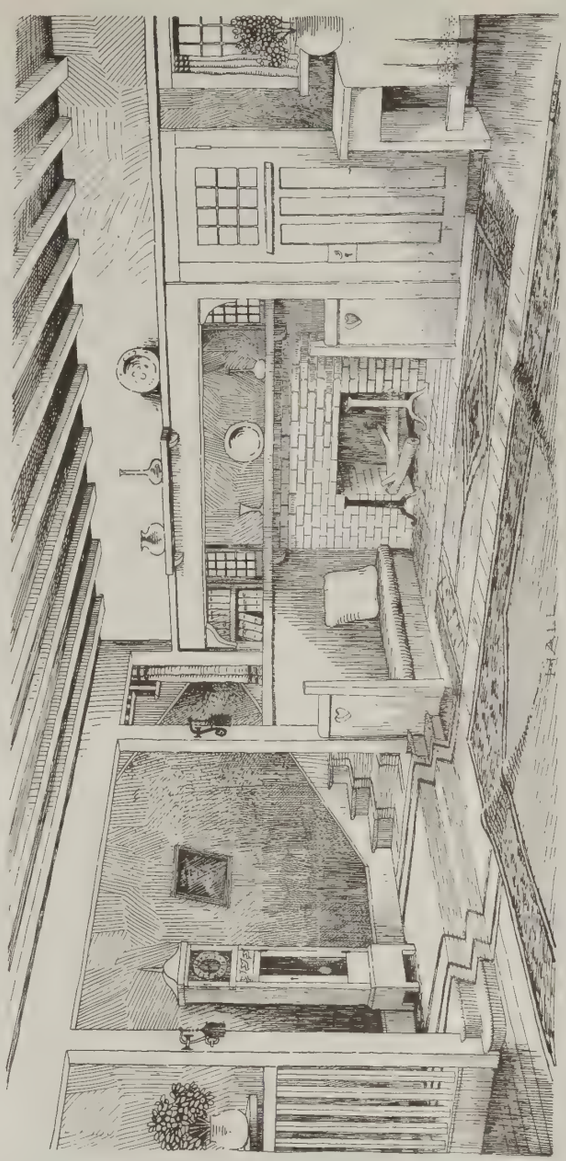


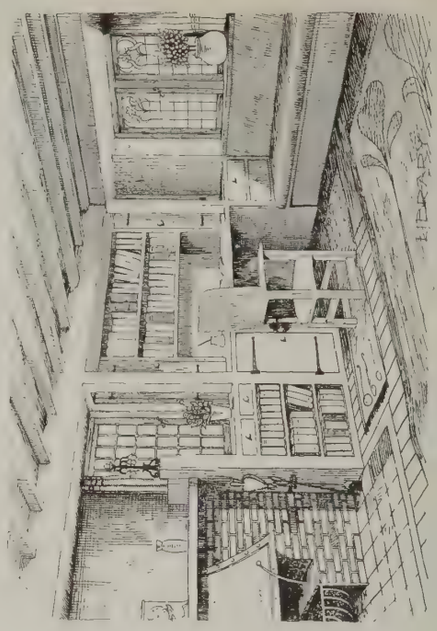
Mr. H. Maring suggests the use of white-faced cement blocks. The somewhat classic lines are well carried out and the red tile of the roof adds a pleasing touch of color.

It is to be noted that a limit of $4,000, not including heating apparatus, plumbing, electric wiring or fixtures, was fixed for the complete building, and it would seem that the designs submitted were well worth the limit.



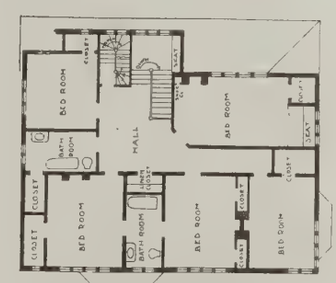
The interest shown in this competition indicates the trend of public opinion toward a house designed to be in a measure at least, fireproof. With incombustible walls, floors and roof, the risk of fire, both internal and external, is greatly diminished. The permanence of a building of this character, with freedom from repairs, does much to make it popular, but nothing does as much as the indication of sound and artistic construction from every architectural point. The people want good buildings, and are learning that good buildings may also be made artistic.





Wm. Drummond, Architect, River Forest, Ill.

H. Maring, Architect, New York.



SKETCHES OF HOUSE FOR MR ADAM Z. ALT. F.G.W. DIETRICH. ARCHITECT. NEW YORK.

BOOK NOTICES

Notice.—All books noticed in these columns may be obtained from this office at Publisher's prices. All postage or express prepaid. Money and address must accompany all orders.)

WOODWORKING FOR AMATEUR CRAFTSMEN, by Ira S. Griffiths, A. B., Supervisor of Manual Training, Oak Park, Ill.; Instructor in woodworking and methods Bradley Polytechnic Institute Summer School, Editor Illinois Manual Arts Association, Chairman Editorial Board, Western Drawing and Manual Training Association. Popular Mechanics Handbooks. Price, cloth, 25c.

Every boy at an early age develops a taste for mechanics, and as the old Yankee whittler said, "Every boy should be able to make things. Knives are cheap and lumber plenty." With the idea of fostering the mechanical taste and producing things useful, the author has prepared this book treating on elementary woodworking, care and sharpening of tools, etc. The preparation of rough stock is shown and when the student student is sufficiently prepared, he is shown the correct methods of making small furniture, such as bird boxes, tabourets, umbrella and magazine stands, tables, cabinets, etc.

The book is written in simple, practical terms, readily understood by those for whom it is intended.

A MANUAL OF TECHNICAL PLUMBING AND SANITARY SCIENCE, by S. Barlow Bennett, Consulting Sanitary Engineer. Third Edition, Revised and Enlarged. Price, $2.00 net. Published by S. Barlow Bennett, Portland House, Jesmond Road, Newcastle-on-Tyne, England.

While one of the oldest trades, and one of the most necessary to our modern condensed civilization, plumbing and sanitation has not been given the attention it deserves. The apparatus and conveniences satisfactory for a village cottage becomes entirely inadequate when the village becomes, as it so often does, a busy village street.

The experience of Mr. Bennett as lecturer on sanitary engineering, instructor in practical plumbing, etc., enables him to treat intelligently the various lines under consideration.

The author takes the reader through the elements of practical science as connected with plumbing and sanitation, the manufacture of materials, physical properties of air and water, leading up to the installation of hot and cold water systems. Heating by hot water, etc., sanitary appliances and sanitary science are discussed in detail, showing the finished work under various conditions and arrangements, and closely allied to this is house drainage and sanitation.

The accuracy of plumbing work can only be indicated on proper tests. As various by-laws specify certain tests, the journeyman must be prepared to make them. Whether a test is required or not, the system should be in such shape that it would pass the most rigid inspection.

While there are many items on which English and American practices differ, the general principles are the same in both. An American reader would not recognize goods of English manufacture, but the essential points are the same. The plumber who understands his work here will recognize many points of excellence in English methods which can be utilized.

FIRE AND FIRE LOSSES.—Instruction Papers, prepared by F. W. Fitzpatrick, Consulting Architect, formerly of U. S. Service; executive officer International Society of State and Municipal Building Commissioners and Inspectors, etc.; American School of Correspondence, Chicago, Ill.

Few men are better qualified to speak or write on the subject of fire, fire losses, fire prevention, etc., than Mr. Fitzpatrick. For many years he has endeavored to point the way to fireproof construction, better construction and a reduction of fire losses. That there is need of active work on this subject is evidenced by the enormous annual loss of hundreds of millions of dollars and thousands of lives, and to the shame of our civilization, 999 out of every 1,000 fires are directly due to carelessness or inexcusable ignorance. It is not a nice thought that we have several times the fire loss of European countries, and it can only be explained that we use only one-quarter the common sense of Germany, France, Italy or Austria.

Mr. Fitzpatrick reviews at considerable length the great fires of the past eighty years and pays particular attention to the recent Baltimore, Toronto and San Francisco conflagrations. In many of our large cities there is today the same risk from fire, and only the slightest attempt to minimize the danger. No wonder Mr. Fitzpatrick says of a certain narrow canyon in New York: 'Think of the havoc fire could play in the very tall buildings both sides of these dismally narrow streets, unless all the windows are protected. Probably not over half a dozen buildings out of many hundreds are so protected, yet nearly all of them are expensively 'fireproofed' as far as the structures are concerned, though the finish is almost invariably of expensive wood and the exteriors are often of granite and marble. These buildings cost hundreds of millions; house thousands of humans, and contents to the value of other hundreds of millions, and offer them *absolutely* no protection from fire. Malignant, criminal, atrocious ignorance or carelessness."

We have only praise for any effort tending to decrease the fire loss through education as to cause and prevention of fires or through better construction. There is room for many efforts along these lines.

RECENT COURT DECISIONS

It is only when the statutory plea has been filed by the owner, setting up that the building is not liable to the plaintiff's debt, that it becomes necessary for the plaintiff to prove on the trial that the provisions of the mechanic's lien act had been complied with by him.—Fay v. Thornton, 76 A. (N. J.) 321.

A contractor's delay in delivering material may give rise to a cause of action for damages which the owner may counterclaim in an action to foreclose a lien therefor, but he cannot defeat the action merely on that ground.—Raymore Realty Co. v. Pfotenhauer-Nesbit Co., 123 N. Y., S. 875.

Under the Act of 1906, the owner in default is not bound personally as under Act No. 180 of 1894, as amended by Act No. 123 of 1896, but only "to the same extent as the surety would have been," and such surety is not bound except as to claims duly recorded within the legal delay. —Louisiana Glass & Mirror Works, v. Irwin, 52 So. (La.) 765.

Proof that a subcontractor furnished an unsafe scaffold, which fell, injuring an employe of the general contractor standing on such scaffold or on an adjoining scaffold, and that the employe was on the scaffold at the suggestion of the general superintendent of the subcontractor, raises the question of the subcontractor's negligence, and the issue must be submitted to the jury.—Huston v. Dobson, 123 N. Y. S. 892.

Under Labor Law (Laws 1897, c. 415) § 18, re-enacted in Consolidated Laws, c. 31, prohibiting any person erecting a building from furnishing any unsuitable scaffold, a building contractor is under the absolute duty of constructing a safe scaffold to afford proper protection to the persons employed to work thereon, and the fall of a scaffold, in the absence of evidence of other producing cause, points to the omission of the duty sufficient to justify a finding of negligence.—Huston v. Dobson, 123 N. Y. S. 892.

Where a building contractor furnishes a scaffold, those entitled to use it may rely on the performance by the contractor of the duty imposed by Labor Law (Laws 1897, c. 415), § 18, re-enacted in Consolidated Laws, c. 31, requiring him to furnish a safe scaffold, and where one lawfully using a scaffold is injured in consequence of the negligence of the contractor, a liability exists independent of the actual employment of the person injured.—Huston v. Dobson, 123 N. Y. S. 892.

Where a building contract provided that the owner might make alterations, subject to the architect's approval, without vitiating the contract, that the architect should issue a final certificate as to the balance due, which should be conclusive evidence of the performance of the contract, and that his decision should be final and binding on all parties, his final certificate is a conclusive determination that the contractors had properly performed their duties according to their contract.—Wiggins v. Columbian Fireproofing Co., 76 A. (Pa.) 742.

Where the person in charge of the work of a subcontractor in the erection of a building, and intrusted with the general superintendence of the work and of the construction of necessary scaffolds, suggested to employes of the general contractor to use scaffolds erected by him to facilitate the subcontractor's work, the employes were justified in using the scaffold because the arrangement was not outside of the authority conferred on such person and the subcontractor was liable for injuries to the employes caused by negligence in constructing the scaffold.—Huston v. Dobson, 123 N. Y. S. 892.

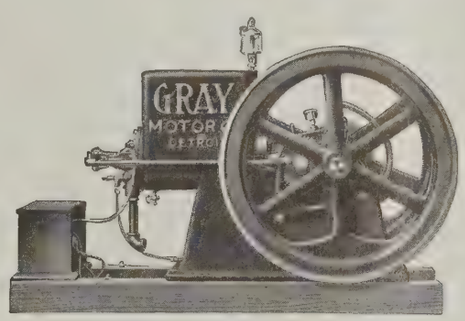
Under the provisions of Act No. 134, p. 223, of 1906, relative to building contracts in cities in this state of over 50,000 inhabitants, a furnisher of materials under a contract with the undertaker, who has not filed a sworn statement of his claim with the owner, and has not caused the same to be recorded, as required by the third paragraph of the first section of said act, within forty-five days after the date of the completion of the building, has not cause of action against the owner in default for not exacting bond and surety from the contractor.—Louisiana Glass & Mirror Works, v. Irwin, 52 So. (La.) 765.

A bill by subcontractors to foreclose a mechanic's lien alleged a contract between the owner and C. and K. as original contractors to build a house, and that one of the original contractors, K., employed complainants as materialmen and mechanics to work on the house. The proof showed that the contract was made between the owner and a lumber company, which was a corporation, and also that K. was not one of the original contractors, but a mechanic employed by C. to do the work, and that he in turn employed complainants to work for him. *Held,* that there was a fatal variance both as to the making of the original contract and as to complainants' employment.—J. C. McCrew & Sons v. Earnest, 52 So. (Ala.) 639.

An estate owning buildings which were destroyed by fire gave a lease to the then tenants for a building to be erected, employed an architect, and contracted with a builder to construct the building according to plans. After the work was commenced, the estate decided to change the floors, putting in a patent floor. The architect received two letters from the patent holders offering to put in the work, giving specifications and guaranty that the floors would carry a certain weight; but the architect did not accept the offer, but requested the builders to submit a proposition to change the floors, and the builders did so, giving an estimate, but making no reference to letters from the patent holders, and the architect authorized the builders to proceed as per the estimate, "said sum to cover the five floors in accordance with the accompanying letters" of the patent holders, and thereupon the builders contracted with the patent holders to put in the flooring to the "satisfaction, approval, and acceptance" of the architect. *Held,* that the contract between the estate and the builders did not include a guaranty that the floors would carry the weight contained in the offer of guaranty of the patent holders, and the builders could not be held liable for a subsequent settling of the floors, due to a smaller weight; the floors having been constructed according to the plans, and the architect's approval having been given after a test made in his presence.—Wiggins v. Columbian Fireproofing Co., 76 A. (Pa.) 742.

TRADE REVIEW

ENGINES FOR CONTRACTORS' USE.



The Gray Motor Company, the well-known marine engine builders of Detroit, Michigan, are now putting on the market a complete line of 2 cycle and 4 cycle stationary engines.

Although they have been catering to this trade for some little time past, it is only recently that they began building 4 cycle engines.

They have been builders of 2 cycle engines exclusively for a number of years, but in supplying the trade with stationary engines it was found to be a better plan to have both 2 cycle and 4 cycle engines, as there are many cases where a 4 cycle is better adapted to the work than two 2 cycle, and vice versa.

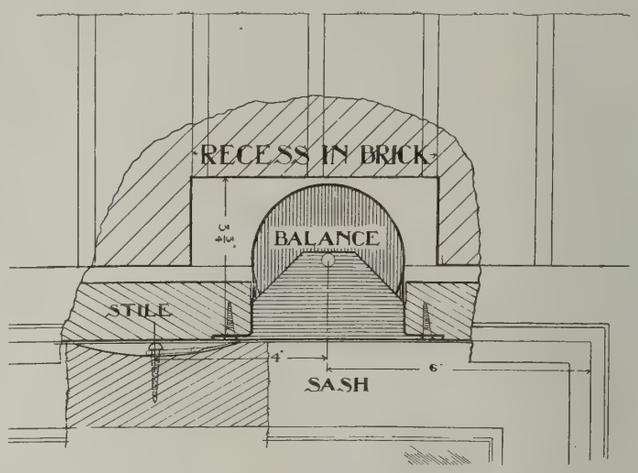
Take the carpenter, for instance, who has a small work shop of his own, with some of the smaller wood working machines that are best adapted to the use of the carpenter; the gasoline engine has proved to be his one salvation, and a 4 cycle engine, such as the one manufactured by the Gray Motor Company, has been found to be particularly well adapted to this kind of work. They are reasonably low in first cost, the upkeep is very slight and the gasoline engine today is so perfected that if a reliable one is purchased there is very little danger of annoyances from unsatisfactory engines. In fact, it will be found that the purchaser really takes no chances at all, as a reliable firm guarantees their product, and as it is only a question of selecting your engine from a concern who is known to be well advertised and financially able to look after the needs of all its customers.

The 4 cycle engine, which we illustrate here, is one of the latest models of the Gray Motor Company and is particularly well adapted to carpenter shops, etc. The illustration is of a 4 H. P. size and is a very complete power plant. It is water cooled and mounted on substantial, well-seasoned wood skids with battery box attached to the skids. The gasoline tank is in the base of the engine and the cylinder and hopper are cast in one piece of the best gray iron, preventing any possibility of leaking joints. The engine is very simple and accessible, has a very sensitive automatic governor which takes care of any variation in the load very quickly and automatically, also cuts off the supply of gasoline and electric current when the engine is running on a light load, making the engine a very economical one to operate. Normal speed of the engine is 350 to 400 r. p. m. Can be instantly

4 H. P. 4 CYCLE GRAY, JR., ENGINE.

increased or decreased between 300 and 500 r. p. m. The starting handle is situated conveniently in the fly wheel, closing up automatically when the engine starts. The engine is painted a light green, skids and battery box a dark red, will operate on kerosene, alcohol, distillate or gas as well as gasoline.

Just to give you an approximate idea of how cheaply one of these engines will do your work, the following data may be interesting: Engine consumes about ½ pint of gasoline per h. p. per hour; 4 h. p. engine running all day under full load will consume approximately 20 pints or 2½ gallons of gasoline which, at 16 cents a gallon, would be 40 cents. Of course, a general user would undoubtedly average not more than four hours a day and the work would, therefore, be turned out for an expenditure of about 15 or 20 cents a day for fuel. These figures, of course, are only to give an idea of what a gasoline engine will accomplish under normal conditions; different conditions and different kinds of work naturally could be expected to increase or decrease the cost, depending entirely upon time and amount of work being accomplished. Any carpenter or builder desiring information regarding gasoline engines should write to the Gray Motor Co., 877 U. S. Motors Building, Detroit, Mich., for their catalogue, and we are also sure you will find them not only willing but well prepared to answer any questions of a technical nature that you may put to them.



SASH BALANCES FOR NEW BUILDINGS.

Architects and Builders have for years been familiar with "Pullman" Sash Balancers. Their mechanical correctness is generally conceded; likewise their durability and efficiency. Their general use has been retarded because individual fitting was necessary, for the reason that each weight of window required a different size Balance. This made it necessary to cut the mortises by hand and made the cost of installation more than that of cords and weights.

The Pullman Mfg. Company of No. 10 Allen St., Rochester, N. Y., has overcome this objection entirely and is now supplying what they term a Unit System Sash Balance. The Unit Balance is made on exactly the same principle as the "Regular" Pullman Balance, of which there are upward of 5,000,000 in use today.

The Unit Balances have a uniform size face plate. This permits the mortises to be cut at the mill, just as mortises for sash pulleys are now cut.

Architects and Builders are welcoming this improvement, for the reason that cords and weights are a continual source of trouble. The weights are bulky and heavy to cart into a building and distribute. Furthermore, when brought to the place needed, they are rarely found

SHOWING INSTALLATION IN BRICK BUILDING. NOTE OMISSION OF BOX FRAME.

to be the exact weight marked on them, if indeed they are marked at all. The labor of stringing cords and getting the weights in place is very much greater than of attaching Unit Balances, which require only the insertion of two screws in the frame and one in the edge of the sash and the putting on of the tape.

The use of "Pullman" Unit Sash Balances is made still more easy by the fact that they are supplied at a flat price per window for all windows in a building. This makes it a simple matter to estimate the cost of Sash Balances, and the Architect or Contractor can see at a glance just what the saving is to be.

Sash Balances require no box frames nor pockets through which to get at the weights. This saving in woodwork, added to the cost of the cords, weights and pulleys in nearly every case will exceed the cost of Unit Balances. In brick, stone or concrete buildings, the saving is material and there still remains in favor of the Balances the less cost of putting in, the greater durability and better appearance of a Unit Sash Balancer.

The Pullman people have just issued a new catalogue with complete drawings showing the installation, which they will be glad to send upon request.

ELECTRIC LIGHTING OF COUNTRY HOMES.

One of the greatest drawbacks to life in the country has been the lack of lighting facilities. The bright lights of the city not only draw the countryman to the city, but hold him there. Dreading the dark rooms, and when the wind blows out the light of the lantern, the dark path, the dark barns with the danger of an overturned lantern, it is no wonder the city holds the country people. Under equal circumstances, the vast majority would live in the country, but the light question has been one of the hardest to overcome.

It is now possible to light the country house as well as the city house, and at much less cost. By means of the Johnson Mfg. Co.'s Lighting outfits, any number of electric lights or connections for motors, heaters, etc., may be installed. By a simple storage battery arrangement a few minutes' attention will insure light for several days. Each complete lighting plant consists of a gasoline engine, generator, storage battery, switchboard and wiring. As some owners already have the engine, this plant can be arranged to be run by it, thereby saving the cost of another engine. The work which can be done by an outfit of this character is practically limitless. The cream separator can be set up in the most available place and the current brought to it. Every part of the house, barn or grounds can be lighted without danger from fires.

As each location varies in its requirements, it is impossible to give any prices except for specific arrangements. The Johnson Mfg. Co., 408 Sharp Bldg., Kansas City, Mo., will be glad to advise anyone who is thinking of installing a lighting outfit, whether for a single house or for an entire farm project.

The fact that complete plants of this character can be obtained should be of great interest to architects, as they can then arrange them for proper lighting country houses, as well as provide the many electric comforts found now only where current from the large power plants are obtainable.

City laundries are discovering that it pays to install electric flat irons, hotels have electric curling irons, apartments have electric chafing dishes, cooking apparatus, etc., and all these are now possible on the farm.

Contractors and builders are deeply interested as the installation of these plants belongs to them. Where no other agents are placed, the contractor should apply and thus be in shape to make his buildings complete in every particular, as well as bring the older buildings up-to-date.

THE JACKSON ALUMINUM LINE LEVEL

Is designed particularly to meet the requirements of all Mechanics in building construction, especially Bricklayers, Masons, Carpenters, Millwrights, Architects, and Cement Workers.

By using the Aluminum Line Level you can take Levels in one-half the time required by the old method of the Straight Edge.

This is possible because the Aluminum Line Level weighs only one-fourth ounce and is easily and quickly attached to a line. Levels thus taken are guaranteed to be accurate on a stretched line from one to forty feet. Besides, from its construction, it can be used as a Pocket Level.

This cut shows the Aluminum Line Level, including Attachment and 40-ft. line. Complete in Leatherette Case.

PRICE $1.00, POSTAGE PREPAID

It is especially adapted for laying out foundations for buildings. It will do the work no other level will do. For sale at hardware dealers, or

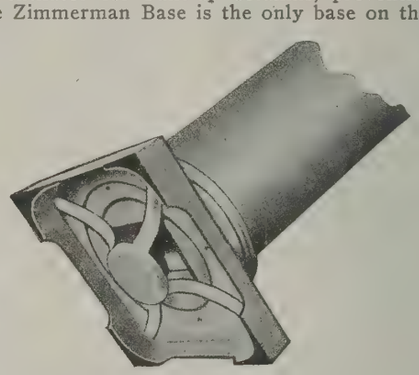
SYRACUSE CORNER BLOCK FACTORY
SYRACUSE, N. Y.

THE NIAGARA VEST POCKET WRENCH.

The accompanying illustration shows the Niagara Vest Pocket Wrench, manufactured by the Niagara Falls Metal Stamping Works, Manufacturers of Hardware Specialties, Niagara Falls, N. Y.

These neat little tools were first sold in May of this year. Their aptness and handiness (even the largest of 8 sizes is not cumbersome in the pocket) together with the very low prices at which they are sold at once created a demand that is evidence of their usefulness and convenience. They fit all nuts, square or hexagon, from 5/16 inch to ¾ inch, and practically last a lifetime.

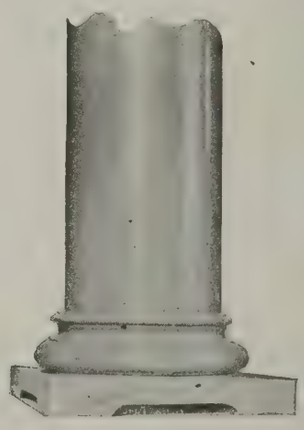


All classes of people, in all occupations, frequently need to use a

wrench, and in no other way can this need be so perfectly and cheaply supplied as with this handy tool. It will handle nuts on the sewing machine, coffee mill, lawn mower, hose reel, clothes line reel, heater, cook stove and range. The householder needs it to tighten the hose joint and stop the leak of the water tap. It is just the tool for the farmer for his corn sheller, threshing machine, mowing machine, harvester, seeder, plow and cultivator. The chauffeur, camper and sportsman will find the Niagara Vest Pocket Wrench just the thing wanted and pat on hand just when wanted. A postal to Dept. N, Niagara Falls Metal Stamping Works, Niagara Falls, N. Y., will bring full particulars regarding sizes, prices, etc.

BASES FOR PORCH COLUMNS.

Our readers will be interested in a description of Zimmerman's Iron Column Base for wood porch columns. It separates the column from the floor, allowing water to run off the porch floor without wetting the bottom of the column, thereby preventing rot and also serves as a ventilator for built-up columns, preventing them from opening. The Zimmerman Base is the only base on the market having a center bearing which supports the required weight without causing the corner supports to sink into the floor.



Anyone who is not fully convinced of the necessity of iron bases has only to take a glance at houses with wood porches that have been built only four or five years. With hardly an exception the columns and the floor have rotted at the junction. The reason is a simple one—there was no protection at the base so that the water could run off. The decay of this "keystone" means that it will soon be necessary to make extensive repairs to the whole structure.

Isn't it strange that while every other part of the house is protected against decay, the columns which first greet the caller should be neglected?

The whole problem is solved by the Zimmerman Iron Base. Its enthusiastic reception by builders and architects throughout the country proves that it is appreciated by them.

This base makes the life of the column equal to the life of the rest of the building. It lifts the column from 1⅞ to 6 inches off the floor and perfectly preserves the architectural effect. Air, instead of water, comes in contact with the column. It greatly enhances the appearance of the veranda, especially when it is painted to match the column. The bases are either round or square, in all sizes and are adapted to any style of column. They are also made in halves for pilasters.

Front view

The cost is insignificant in comparison to the saving they afford. Circular "J" will be mailed on request by the Syracuse Corner Block Factory, Syracuse, N. Y.

Asbestos "Century" Shingles

"THE ROOF THAT OUTLIVES THE BUILDING"

The average property owner badly needs expert advice in choosing his roof.

He's too apt to assume that every roof is as good as it looks when it is first put on.

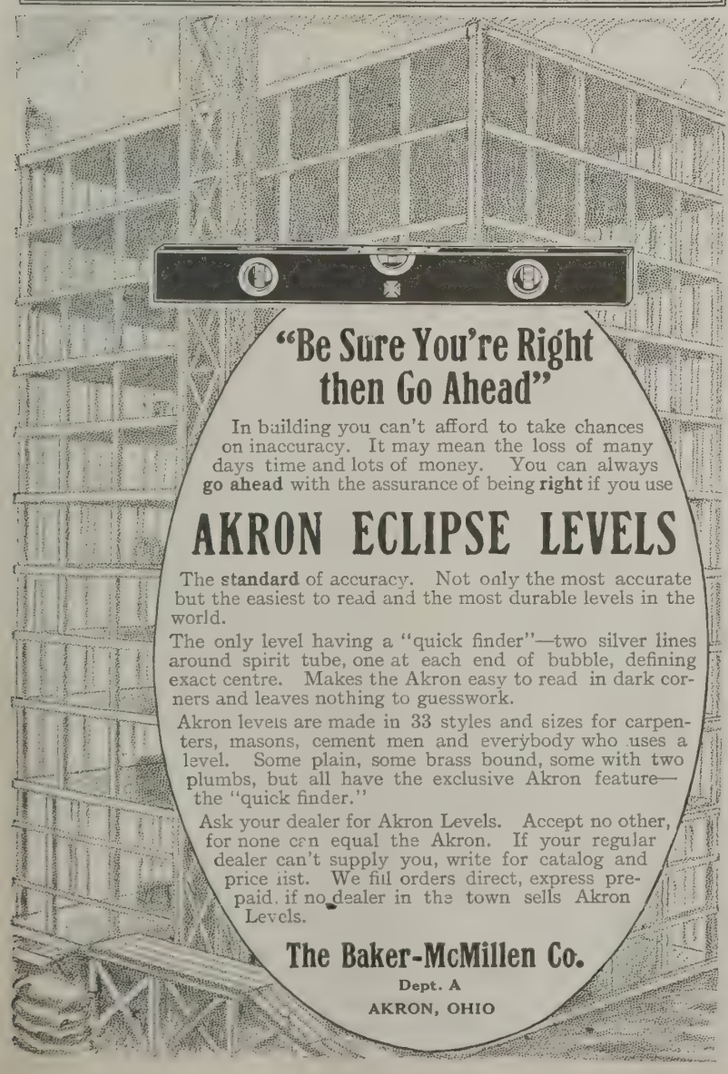
It's only when bills for repairs and painting pile up that he realizes his mistake.

Asbestos "Century" Shingle Roofs—Five Model Cottages, Esmond Co., Inc., Enfield, R. I. Architects, Hilton & Jackson, Providence, R. I. Contractor, P. Oscar Nordquist, Providence, R. I.

Asbestos "Century" Shingles are the only roofing in the market that combine architectural beauty with *absolute and permanent protection to the building.*

Asbestos "Century" Shingles are thin, tough and elastic shingles of *reinforced concrete.* They are the first and only practical light weight roofing ever made of this indestructible material.

They are proof against fire—against weather—against time. They need no painting or repairs.



Asbestos "Century" Shingles are adapted to all architectural styles. They come in many shapes, several sizes and *three colors*—Newport Gray (silver gray), Slate (blue black) and Indian Red.

It's worth your while to talk with a responsible roofer about Asbestos "Century" Shingles—OR WRITE US. Send for Booklet K & M, 1911.

"Be Sure You're Right then Go Ahead"

In building you can't afford to take chances on inaccuracy. It may mean the loss of many days time and lots of money. You can always **go ahead** with the assurance of being **right** if you use

AKRON ECLIPSE LEVELS

The **standard** of accuracy. Not only the most accurate but the easiest to read and the most durable levels in the world.

The only level having a "quick finder"—two silver lines around spirit tube, one at each end of bubble, defining exact centre. Makes the Akron easy to read in dark corners and leaves nothing to guesswork.

Akron levels are made in 33 styles and sizes for carpenters, masons, cement men and everybody who uses a level. Some plain, some brass bound, some with two plumbs, but all have the exclusive Akron feature—the "quick finder."

Ask your dealer for Akron Levels. Accept no other, for none can equal the Akron. If your regular dealer can't supply you, write for catalog and price list. We fill orders direct, express prepaid, if no dealer in the town sells Akron Levels.

Ready-To-Lay

Burmite

(REG. U. S. PAT. OFF.)

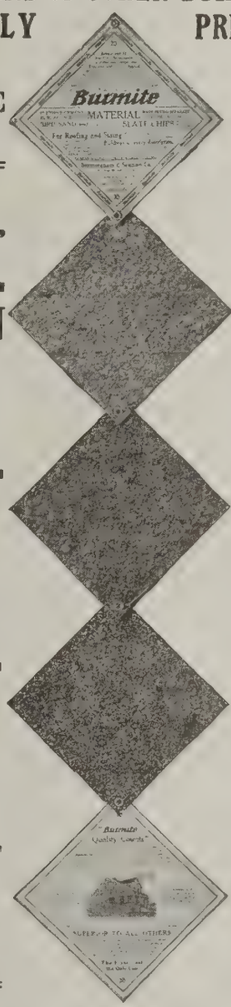
A FLEXIBLE-CEMENT-BURLAP INSERTED MATERIAL FOR

ROOFING AND SIDING

Buildings of Any Kind of Construction

—Be They New or Old

Recognized and acknowledged to be the most Durable, Practical and Inexpensive for use as a roofing and siding material. **Burmite is Guaranteed for 10 years without Coating or Painting,** and if properly laid will last from 20 to 25 years. **"Burmite" lasts longer than shingles—costs less, lays smoother; looks nicer and requires no paint to preserve it. Can be laid over old shingles or tin;** is odorless, will not "run" on steep roofs; and on account of its unusual flexibility is especially well adapted to flat or uneven surfaces.



Used in any climate, can be applied in cold or hot weather without danger of buckling, expanding or contracting.

HOW STEEL BINS AID IN FIRE PROTECTION.

The matter of fire protection is of the utmost importance in every business, but it is a striking fact that thousands of merchants and manufacturers take no cognizance of the necessity of this protection. They are generally disposed to let well enough alone—inasmuch as they "haven't been burned out yet, so let everything take care of itself as it is."

These are the men who, after the disaster that comes unexpectedly upon them and overwhelms them, ruefully look back upon their old time optimistic complacency and condemn themselves for being too narrowminded to fortify and protect themselves against the fiery foe.

Such examples as these have opened many eyes and to the doctrine of forethought is due much of the success of steel. Business men, heeding the necessity of protection against every un-

VIEW OF TWO ASSEMBLIES OF BERGER'S SECTIONAL STEEL BINS AND SHELVING. NOTE BIN BOARDS TO RETAIN SMALL PARTS.

toward contingency, are building bulwarks of steel about them. They have discarded wood and others are following their example.

So, as the transition progresses, it reaches out into every office, store, factory, warehouse, jobbing house and so on down the list. The cry on every hand is "Fireproof—it must be fireproof!" Business men demand fireproof buildings because they want their property, their stock, their business thoroughly protected.

An essential in this all-around fireproofing is the discarding of everything that is a fire contributor. One of the latest and newest products of this kind placed on the market for store, factory and warehouse fixtures is the steel bin, manufactured by the Berger Manufacturing Company of Canton, Ohio.

Steel bins are coming into favor for storing small stock of every description in bulk. Hardware dealers and other merchants are using them, while they are being introduced into many factories

BERGER'S SECTIONAL STEEL BINS BEING SUBJECTED TO A SEVERE TEST.

where it is essential that small parts be kept conveniently at hand. They are constructed of steel and reinforce the other steel construction of the building, for they do not feed flames but do assist in the general plan of protection.

One of the biggest manufacturing companies in the great Pittsburg industrial district long ago adopted a plan something like this, of having steel compartments in a great room, protected on all sides with steel—like a gigantic vault—for the storage of valuable blue prints.

BAYONNE OR GULF STREAM

JOHN BOYLE & CO.'S Awning Stripes have been the Standard for 50 years.

It Costs Less to Lay—

a Slate Roof and it's easier and less expensive to keep in perfect condition during the whole life of any building—than to get equal results with any other roofing material you can think of.

Furthermore—any roof structure strong enough for a roof of shingles, tin or iron, is fully strong enough to hold a roof of slate that never wears out.

Sea Green or Purple Roofing Slate

is the toughest and best roofing slate ever quarried. It is easy to handle—easy to lay—and outlasts any building. Its first cost is the only cost; there are no paint bills—no repair bills—no bother—no worry. Once laid it *never* wears out; is fireproof, lightning proof and absolutely impervious to climatic changes.

Tell us to send you the *proofs*—and tell you why it will pay you—how it will satisfy your trade; and send you our booklet "Roofs" giving specific and interesting facts on comparative roofing costs and values. Write for this information today. Address

METHOD OF TINTING CONCRETE.

Considerable interest is being shown in the tinting of concrete when it is used for residential purposes. Undoubtedly the work can be done successfullly with certain colors. Concrete can be tinted green, for instance, by the use of cromium oxide, in proportions of approximately 5 to 8 per cent of the weight of the cement used. A yellow or buff tint can be obtained by the use of French ocher in the percentage of 4 to 10, according to the shade desired. Red is obtained by the use of red oxide of iron, that manufactured in Germany or France preferred. A pure white concrete, says Contract Record, can be made by the use of 1 part white Portland cement and 2 parts marble screening, tough, hard marble preferred, the screenings to pass through a No. 8 screen and be collected on a No. 40 screen. It should be mixed fairly wet so that it will run into the molds. The molds should be slightly rocked and jarred, so as to expel the air bubbles. For some characters of work the concrete can be made not quite so wet, but of about the consistency used by brickmasons in laying brick, and pressed in the molds. As soon as the concrete is hard, say in three or four days, it should be rubbed well with a fine terrazzo polishing stone. This will give the appearance of a white polished surface. Although the cement itself will not have been polished, each particle of marble will present a polished surface.

PRIZE WINNERS.

In the April issue of THE NATIONAL BUILDER we published the terms of a competition in which S. C. Johnson & Son, Racine, Wis., offered prizes aggregating $150.00 for the best reasons for using Johnson's Wood Dye and Johnson's Under-Lac. The merits of these finishes

H. R. BRUNELL, WINNER OF FIRST PRIZE

were so generally known that the manufacturers received a very large number of replies, and have finally come to a decision as to the relative merits of the answers submitted.

Mr. H. R. Brunell, 916 Bloomfield street, Hoboken, N. J., was fortunate in securing the $25.00 prize.

Closely following Mr. Brunell in order of merit, with $10 each as an award, come:

Stanley Sivers, 606 Third street, Albany, N. Y.
F. B. Carter, General Delivery, Portland, Ore.
F. P. Connolly, 151 South Water street, York, Pa.
Albert Borchardt, Monticello, Ark.
H. W. Richards, 164 Oak street, Elgin, Ill.

The third prize winners, $5.00 each, were:

Christopher T. Sullivan, 46 Stewart street, Fall River, Mass.
Thomas A. Cooper, 308 McClellan street, Schenectady, N. Y.
Joseph Denno, Alpena, Michigan.
R. F. Flannery, 325 Poole avenue, Long Branch, N. J.
J. N. Humble, 816 E. Cachela Poudre st., Colorado Springs, Colo.
Elmer Rosengren, 404 Anson street, Marshalltown, Iowa.
J. White, 6121 Sangamon street, Chicago, Ill.
H. Edwards, Jupiter, Fla.
H. A. Baldwin, Box 589, Austin, Texas.
Jesse J. Jackson, Box 37, Teague, Texas.

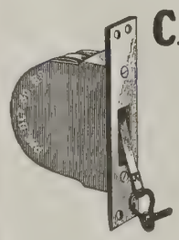
The following were given the fourth place with $1.00 each:

J. P. Rowden, 313 E. 4th street, Texarkana, Ark.
George Voss, Benson, Nebr.
Charles F. Hoefer, 122 Mystic avenue, Medford, Mass.
C. Churchill, 148 W. 16th street, Erie, Pa.
R. T. Hill, 3117 Forest avenue, Chicago, Ill.
E. G. Myers, 41 Elm street, Plattsburgh, N. Y.
J. W. Rainsford, 3704 Park avenue, Nashville, Tenn.
Anton Hoffstadt, 3212 Addison avenue, Chicago, Ill.
H. A. Struebing, 2739 Lafayette avenue, St. Louis, Mo.
Richard Holle, Jr., 708 Eighth avenue, Clinton, Iowa.
J. H. Clark, 412 East Main street, Bradford, Pa.
Wm. Van Valkinburgh, 1221 Watt street, Schnectady, N. Y.
R. McEwartson, 6610 Hartwell avenue, Chicago, Ill.
Everett March, 217 Somerset street, Plainfield, N. J.
Richard Smith, 3 South Central avenue, Wollaston, Mass.
H. Laycock, 77 Southgate street, Worcester, Mass.
D. W. Edwards, Box 1140, Twin Falls, Idaho.
Frank Gordon, 127½ Stockton street, Brooklyn, N. Y.
E. C. Monroe, Berlin, N. J.
H. C. Faber, Monongah, W. Va.
Elmer Hahn, 71 Main street, Hudson Falls, N. Y.
Fred Bennis, 319 Spies avenue, Menominee, Mich.
A. S. Joynes, Fortress Monroe, Virginia.

To those unacquainted with the use of Johnson's Wood Dyes, their effects are a revelation. The ease with which they can be applied make them favorites with both the amateur and the professional painter. We understand that the manufacturers, S. C. Johnson & Son, Dept. N. B. 7, Racine, Wis., will be glad to send their color panels and samples of both the Dye and Under-Lac to readers of THE NATIONAL BUILDER.

WOOD MANTELS AND FIREPLACE FIXTURES.

The artistic effect of a mantel with its cheerful fireplace is frequently the keynote of the home atmosphere. There are few months in the year in which a fireplace cannot be used to advantage, and a greater part of the year a grate fire is necessary to bring the temperature of the room above the chill point. The beneficial effect of ventilation must also be considered, for pure air is more necessary than heat as a rule.



Many as the forms of fireplaces are, there are almost as many in which the construction is not perfect, the draft is not good, and the appearance does not add to the beauty of the room. For all these defects there is no excuse, for there are reputable firms manufacturing mantels and fireplaces in which the design, construction and action leaves nothing to be desired.

The Huber Builders Material Company, 39-43 Vine St., Cincinnati, have been manufacturing the highest grade of mantels and fireplaces for many years. In their latest catalogue are shown many pleasing designs in many styles, and in several woods suitable for almost any position. Aside from the high quality of their goods, the Huber Builders Material Company have an ideal method of transacting business, and it will be to the interest of the contractor or builder who anticipates installing a mantel to write to them. A postal will bring their catalogue and a prompt answer to inquiries.

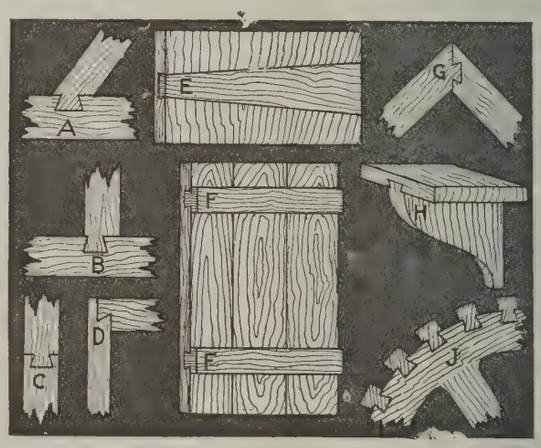
STANLEY DOVETAIL TONGUE AND GROOVE PLANE.



A new and novel tool which accomplishes a result sought for many years by wood workers in general, namely—to form a dovetail tongue and groove with one hand tool.

This result was reached by designing a plane which at one setting cuts a groove with a cutter having a horizontal edge guided by an oblique fence, and in the other setting cuts a tongue with a cutter

having an oblique edge of the same angle guided by two fences at right angles to each other, one being parallel to one side of the cutter.

The operation of the plane is simple, and the accurate and perfect fitting joints obtained, both parallel and tapering, will convince the operator of the utility of this unique and original tool. Below are shown some of the numerous kinds of Dovetail Tongue and Groove Joints that can be made with its use.

A Dovetail tongue and groove joint with the groove cut in the regular manner, and the tongue cut on a bevel, used for supports.

B Dovetail tongue and groove joint with unequal shoulders or a joint with a regular groove, but where the tongue is offset.

C Dovetail tongue and groove joint as can very often be conveniently used when one is forming an end to end timber match.

D Dovetail tongue and groove half joint, frequently used by carpenters to a very great advantage in concealed nail work.

E Dovetail tongue and groove joint as applied to a flush key batten, where used in strengthening wide, thin boards across the grain.

F Dovetail tongue and groove joint as it is very often used to construct a batten on doors made of several boards, etc.

G Dovetail tongue and groove joint where both the groove and tongue are cut on a beveled surface, making a strong corner.

H Dovetail tongue and groove joint shown in one of its most useful applications, that of a bracket supporting a shelf.

J Dovetail tongue and groove joint as applied to the setting of gear teeth around the outer rim of any gear pattern.

The manufacturers of this unique tool have issued a very attractive circular containing a detailed description, as well as complete instructions for operating, and will be glad to send same to anyone interested. Address—Stanley Rule & Level Co., New Britain, Conn.

Build Artistic Stairways From Gordon-Van Tine Stock!

Save 50%! Special Millwork Catalog FREE

A Flight of Stairs Complete for $23.93

Our Stair Department Will Save You Big Money

Through our ceaseless efforts of selling reliable stairwork at cost plus one small profit, we have been able to produce and sell stairwork at prices which leave a handsome profit for the contractor. In our Grand Free Millwork Catalog we itemize individually, each and every article required for the stairs, and explain fully just how this material comes to you and attach net prices. With this information at your command, an infinite variety of arrangements of stairs can be figured within a few moments, and you know the exact cost without entrusting your interest to any outsider.

The fact that part of this material is already machined ready to go right into the stairs, reduces the erecting cost very materially. We use only thoroughly kiln-dried material in making up the different parts of this stair stock, and only the most skilled and expert mechanics are employed in the production of the finished article. By using kiln-dried lumber you avoid any of the annoying effects of shrinking or coming apart of the stairs after they are put in the building. The itemized list for a flight of stairs which is given on this page, shows you at a glance how reasonable the material for a complete stairs can be purchased.

The fact that you have had no previous experience in the stair building line should not deter you one moment from learning its simplicity now. If there are any points which are not practically clear to you regarding the proposed stair for which you are in the market, write us, and we will give you the advice of an expert stairbuilder.

Vast Assortment of Oak and Yellow Pine Stair Material

Our stock designs of Stair Newels, Rails, Balusters, Steps, Risers, Face and Wall Stringers and miscellaneous materials in Oak and Yellow Pine is very complete. A line which is at once adapted to the swell and modest cottage or most elaborate home.

Correct in Every Detail

We call particular attention to the style of construction, for instance, of our posts; the correct size of all mouldings, in order that the assembled effect may be harmonious and complete. Likewise, the turning of the balusters and shape of rails are especially adaptable for these specific purposes.

With the styles illustrated, an infinite variety of arrangements of stairs is permissible, and it is a very rare exception when special work will be required for any particular purpose. Our designs are modern and up-to-date. All Newels are hand smoothed and made from thoroughly kiln-dried stock. All carvings are handmade and not composition ornaments. Every Newel from one-inch lumber, with glued lock joint. Height of all starting Newels 4 feet, with 8x8 base and 6x6 shaft, suitable for open or closed stringboard. Base of post, 20 inches long, allowing one or two risers. Every Newel wrapped in paper and carefully packed. The stock is all thoroughly machined, well kiln-dried and can be shipped promptly.

Office and Showroom, 1824 Milwaukee Ave., CHICAGO

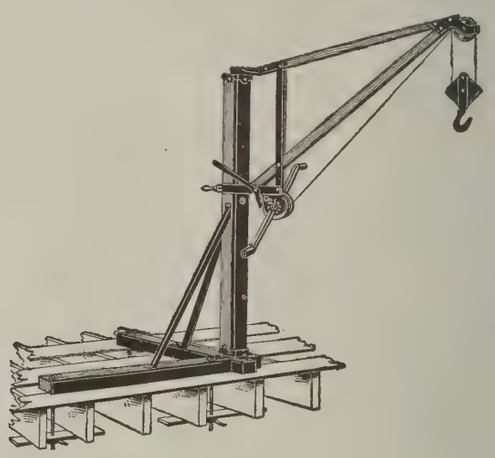
A FREE SAMPLE OFFERED.

Welt & Sons Paper Company of Detroit are offering to send a free sample of their Amafibre Building Paper to every contractor and builder who will write for it.

Amafibre is really a very superior building paper.

As the name implies it is a fibre paper very strong and tough. It is also very light and these two qualities, lightness and toughness, make it easy to handle, hence recommend it to the man who has the actual work of putting it on to do.

Amafibre is waterproof, windproof and largely soundproof. It is very durable and once in place stays as long as the house lasts.



It is a sulphite paper for use in any place where building paper is usually applied—and enjoys even a wider range of usefulness than ordinary building papers, owing to its toughness and weather proof qualities.

Contractors, builders and others who are interested are invited to write to the makers for a sample showing quality and texture.

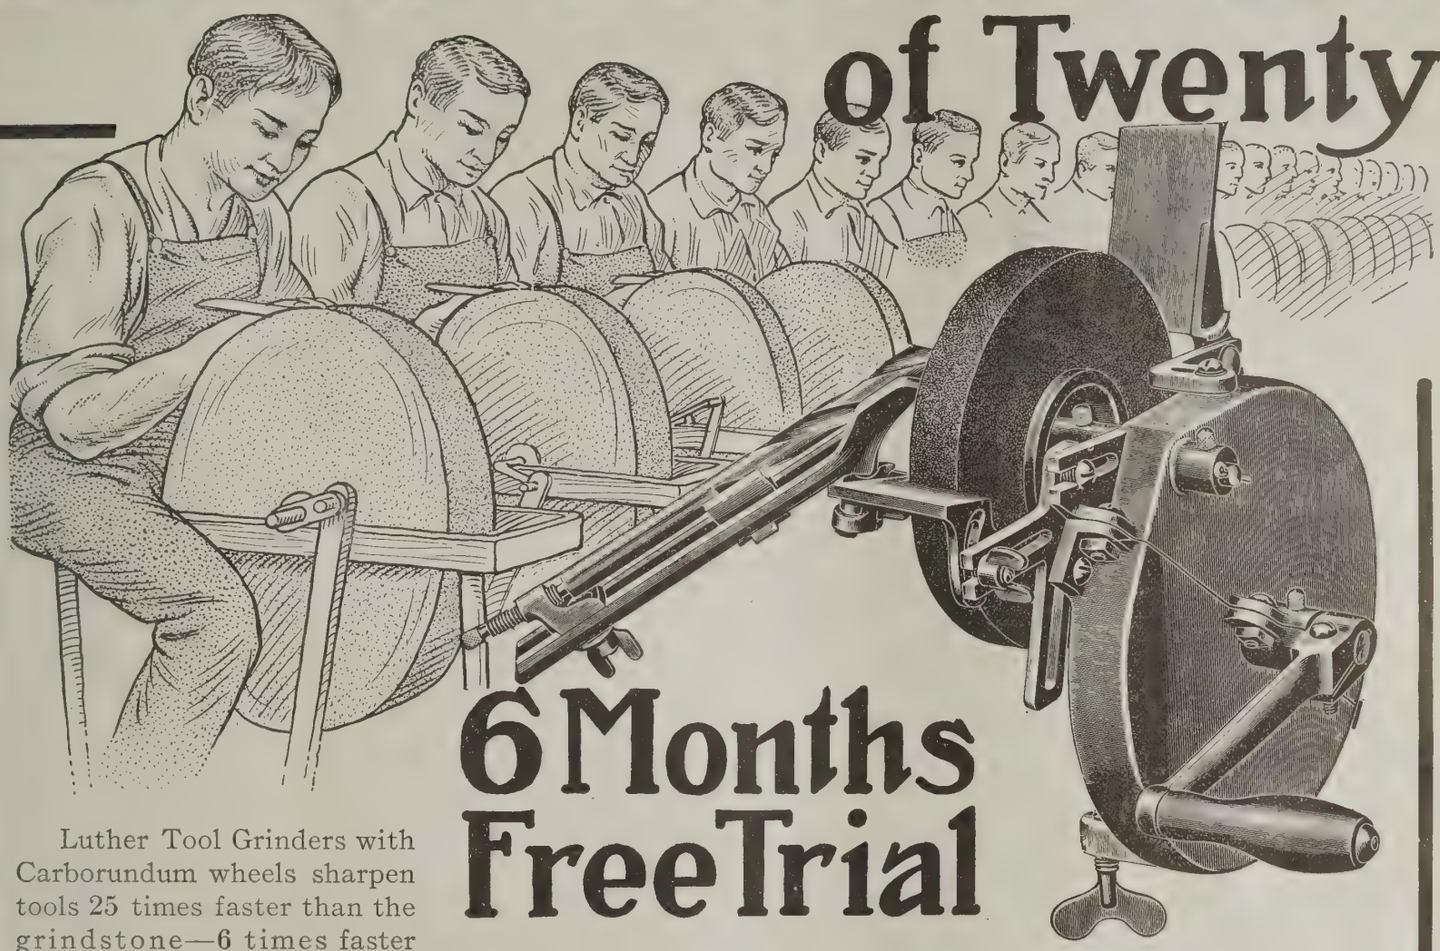
MODERN METHODS IN BARN RAISING.

The old time builder can tell you of the "barn-raising" he attended, the celerity with which a swarm of workmen raised the separate pieces and bents into place, and he will also tell you that it required as much muscle as brains to erect buildings in those days. Possibly a cumbersome block and fall constituted the entire mechanical equipment necessary to construct the building. The rest was left to main strength and numbers coached on by the leader, trying to keep his gang ahead of the other side.

With the advent of modern conditions, however, many customs have more or less dropped out, and new ones take their place. It is no longer possible to secure a large number of skilled and muscular workmen who are willing to work at top speed in competition for glory mainly. Labor must be paid for as used, and it becomes necessary to employ fewer men for a longer period. To raise the heavy framing, mechanical aids are necessary to displace expensive manual lifting, and this is best done by means of a portable derrick. One of the popular styles of derricks is shown herewith. The manufacturers, Sasgen Brothers, 2053-57 Racine avenue, Chicago, Ill., advise us that contractors everywhere are enthusiastic over the variety of work to which this derrick is adopted. This particular pattern, known as the Light Weight Champion, weighs only 250 pounds, and has a lifting capacity of 1,500 pounds. A derrick of this character will quickly save its cost in raising material, window frames, girders, etc. Mention the NATIONAL BUILDER to Sasgen Brothers, will secure detailed description of this and other labor saving devices which the up-to-date minute contractor should not overlook.

SASGEN BROS.' DERRICK WILL SWING A COMPLETE CIRCLE.

THE ECONOMY OF FIREPROOFING.



The fireproof roof, as a part of fireproof construction throughout, is coming to be regarded as a profitable investment. The elimination of fire insurance premiums for a few years will go far toward paying for the added cost of a fireproof building. In short, prevention is better than cure, and the best way to deal with the fire problem is to make fire impossible.

A contemporary writer has well said that the greatest bugbear of the mill owner whose factory is not of the modern concrete fireproof construction is the ever-present fear of fire. On account of this fear and the desire to lower insurance premiums, there has resulted the investment of thousands of dollars in the insallation of sprinkler systems and their maintenance. Such a tremendous investment is but a small part of the cost of fire inspection, the maintenance of other equipment, and the organization and pay of private fire companies. All this expense could be forever eliminated by a thoroughly fireproof construction.

A recent consular report says that there are no wooden structures in Cologne, Germany. The buildings 400 to 600 years old are not wholly fireproof, but of slow-burning construction; all buildings erected now are of brick, stone, or cement and absolutely fireproof. Wooden stairways are not permitted in any except single residences of two stories; all others must be of iron or cement. There has not been a dwelling house burned in Cologne for many years, fires in most instances being confined to one room.

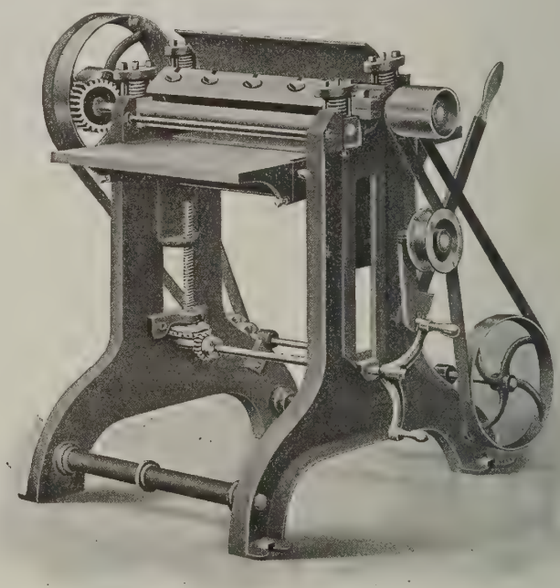
S. C. Johnson & Son, Racine, Wisconsin
"The Wood Finishing Authorities"

ATLAS OAK FLOORING.

Changing styles in ornament and design are still holding on to one of the best features of modern construction. In the treatment of floors the substantial oak floor which has stood the test of thousands of feet is still the model for future use; carpets are fast disappearing as a floor treatment, and are giving way to polished hardwood.

In many places a good soft wood such as pine is already in place, but lacks the finish such as only an oak floor can have. For such places a thin oak flooring ⅜-inch thick can be laid directly on the old floor, giving the required surface without interfering with the doors, base trim or decorations.



The Wildberg Lumber Company, Ninth and Eggleston avenues, Cincinnati, Ohio, have long been identified as distribution of the highest grade of flooring. At present their Atlas Brand is meeting with especial favors. The same care used in manufacture is used in preparing it for shipment and it is not unusual for them to crate the flooring to insure its delivery in first class condition.

Before placing an order for oak flooring it will be well for the contractor to get their ideas and prices. They can probably refer you to a nearby dealer who handles their product and if not they will furnish it direct.

THE GEM PLANER.

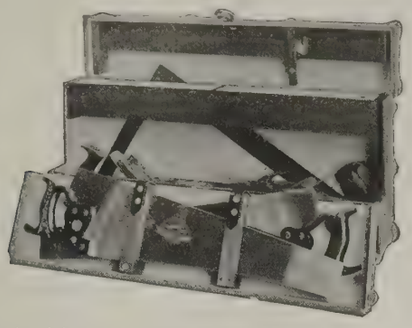
This cut shows the Gem Planer built in four sizes to plane 12½, 16, 18 and 20 inches wide, up to six inches thick. The speed is adjustable, making it work well on hard or soft, green or dry, wood. The location of two feed rollers, one before and one behind the cutterhead, insures even feed and carrying the lumber clear of the machine after the cutterhead has completed its work.

The Frank Machinery Company, Buffalo, N. Y., was established in 1854 as Frank & Company, thereby qualifying as one of the pioneers in the woodworking machinery line. The rapid development of the enormous forests of the United States required quantities of wood-

working machinery of the highest and heaviest grade, and this company has kept well in front in the production of machinery adapted to the use of the American mills. At the present time they are building a complete line of woodworking machinery, a line of planers from 8 inches to 42 inches in width and weighing from 200 to 12,000 pounds. They believe their line of medium-weight, medium-price tools is the largest on the market and also the best. The broadest and strongest possible guarantee covers all their products. The smaller tools and machines, such as planers, jointers, band saws, and saw benches are especially designed for contractors' use, and to meet the needs of various jobs, are built in various sizes.

The increasing use of machinery by even the smaller contractor is evidence of the time and money saving qualities of machinery. The independence from the planing mill, when a few odd pieces are wanted, is one of the striking qualities of the smaller machines. Many large jobs can be gotten out on a comparatively small shop equipment, for it is evident that the large job gives the wide-awake contractor a chance to prepare some weeks or months in advance.

We understand that the catalogues of the Frank Machinery Company will be sent to contractors and builders free when the NATIONAL BUILDER is mentioned, and we would suggest that those anticipating the equipment of a shop write to the Frank Machinery Company for advice on the matter.



INDESTRUCTO TOOL CASES.

For many years we have been accustomed to the sight of a carpenter carrying his tools to a job in an open wood tray with a square rising inches above the other tools, and saws sticking out of one or both ends, and possibly a brace and bit hanging by one corner. Some others would come around with a heavy chest, two-man size, which would be dragged from place to place as the work required. It is no wonder tools were lost or left behind, or the heavier tools left at home to be brought down later.

In the Indestructo Carpenters' Tool Cases, as made by Wedell & Boers, 157 Jefferson avenue, Detroit, Mich., we find a case which overcomes many of the objections to other forms of carrying cases.

PASTE THIS DOME ON LETTERS THAT YOU WRITE ADVERTISERS. IT WILL HELP.

Composed of three-ply veneer covered with heavy canvas and painted in attractive colors, it has the appearance of prosperity and good workmanship. Bound with steel, with re-enforced corners, secure locks and catches, and a firm handle, the case will stand a vast amount of heavy service. Its lightness permits carrying more tools and the shape, not unlike a suitcase, makes easy carrying. The in-

side is arranged with separate compartments for saws, planes, levels, square, chisels, bits, etc.

The case is made in two regular sizes, to take 26 and 28-inch saws. Special sizes for larger tools and outfits can be made up at slightly higher prices.

We would suggest that every workman who must transport his tools frequently write to Wedell & Boers, and see just how it is to their advantage to have one of these excellent tool cases.

ARTISTIC METAL CEILINGS.

With the rapid increase in number of buildings, offices, etc., which must be made more or less fireproof or fire resisting, the demand for metal ceilings has increased. Primarily designed only to retard fire, the possibilities of metal ceiling and plates from an artistic and decorative standpoint, have evolved a large number of most excellent designs.

For the manufacture of plates suitable for decoration, heavy

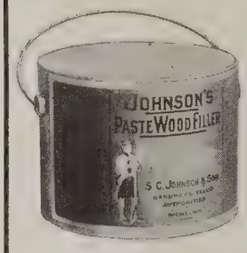
BANKING ROOM WITH METAL CEILING.

presses and accurate machinery is required, while to produce the variety of designs required by a discriminating public, an enormous amount of dies, patterns, etc., are necessary. It naturally follows that only those firms especially adapted for doing a large business of the better class can hope to compete for general work.

The Milwaukee Corrugating Co. of Milwaukee, Wis., and Kansas City, Mo., has long been favorably known among the users of stamped metal work. Their latest catalogue shows many beautiful designs of metal ceilings suitable for various purposes. Among others we find the Banking Room illustrating this article.

The art catalogue of the Milwaukee Corrugating Co. is, we understand, sent free upon mention of the NATIONAL BUILDER.

SEVERE TEST OF UTILITY WALL BOARD.



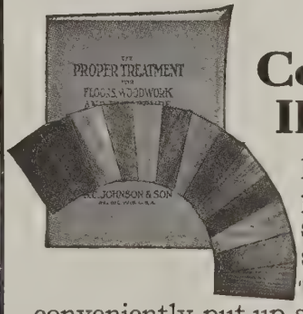
A test that proves very conclusively the imperviousness of Utility Wall Board against the extreme of heat and cold and dampness, has just been completed by Mr. C. A. Heppes at the facftory at 4502 Fil-more street, Chicago.

The hardest problem that wall board manufacturers have to solve is the problem of making a board that will not shrink or warp when subjected to extremes of heat and cold, and that will not absorb moisture.

Six months ago Mr. Heppes felt very confident that he had solved this problem. In order to satisfy himself absolutely, however, he decided upon a test which is probably about the most severe to which wall board was ever subjected.

He selected a thin brick wall in the most exposed portion of his factory building and attached the wall board to this wall, putting it on in the ordinary way, as close to the bricks as possible. He then covered the wall with wall paper so that the slightest sign of shrink-

Write Us Now For Free Samples of Johnson's Artistic Wood Finishes



Johnson's Paste Wood Filler

is made in five shades for filling the grain of all wood, soft and hard. Manufactured from the best and most expensive silex, linseed oil and best Japan dryer and guaranteed to give satisfaction.

All wood which is to be finished natural should be given a coat of Johnson's Natural Paste Wood Filler No. 10 and a finish-wax, Under-Lac and Wax or Under-Lac and Varnish.

We recommend the use of our colored shades of Paste Wood Filler where a golden oak, dark oak and Antwerp finish is desired on hard woods, also for use over Johnson's Wood Dye where a filled grain effect is desired.

Ask your dealer for a free sample of any shade of Johnson's Paste Wood Filler

Johnson's Color Panels and Illustrated Book

Let us send you free a complete set of wood panels showing all shades of Johnson's Wood Dye on various woods. These panels are conveniently put up so that you can easily show them to prospective customers. By doing so we are sure you will procure many contracts at profitable prices for work to be finished with Johhson's Artistic Wood Finishes. The dye *always* matches the panels.

We will also send you a copy of our new book illustrated in many colors and containing color plates of the dye. This book gives full instructions for finishing and refinishing all wood—soft and hard. It is invaluable. Call upon your leading paint dealer for samples, wood panels and book. Or write us giving your dealer's name and we will send them to you from Racine. Ask for booklet Edition N. B.-8.

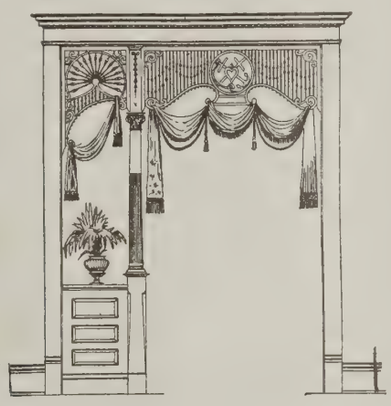
S. C. Johnson & Son, Racine, Wis.

"The Wood Finishing Authorities"

PASTE THIS DOME ON LETTERS THAT YOU WRITE ADVERTISERS. IT WILL HELP.

ing or warping would show immediately. Next he placed a row of steam pipes about an inch from the wall along its entire length. These pipes were used to heat the room and, of course, became very hot during the day and cold at night. All this was done in January of this year. The outside of the wall, of course, was subjected to the extreme cold of the winter weather, while the inside was hot from the steam pipes. At night both the inside and the outside were subjected to the cold. Later in the spring the heat in the steam pipes was turned off and the moisture from the inside of the factory combated the cold from the outside.

After six months of this kind of severe treatment the wall board shows not the slightest sign of shrinkage or warpage. It is almost impossible to tell even by feeling where the joints have been made and even in the corner, where is the severest test, the wall paper does not show any sign of pulling or cracking.



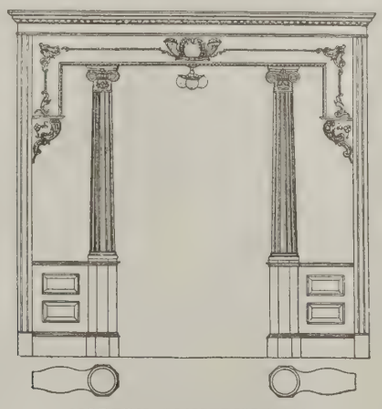
It is hardly possible that plaster or any other kind of wall finish could have stood up so perfectly under so severe a test, and the result is certainly one of which the manufacturers of Utility Wall Board may well be proud. Any wall finish that will stand up for six months under such extreme conditions is as nearly perfect as could well be expected.

STYLES IN GRILLES.

Forty, thirty and twenty years ago, the presence of a grille was about as necessary in a complete home as the front door, and was the keynote for the decorations of the principal rooms. The delicate fret-work was frequently made a background for the most expensive hangings and draperies. Such a grille is shown in this article.

The changing fashions in buildings has made its impression on the interior decorations as well as on the exterior. The elaborate moulded casings have given way to plainer lines, and the grille, too, felt the changing artistic hand.

Today few of the grilles show the delicate tracery, spindles, etc.,



THE STYLE OF 30 YEARS AGO.

of former days, but in its place we find more of the solid, dignified, heavier columns of more nearly classic design. The education of the masses, as well as the designers feel the effect of good design and the restful lines of the present details do not need extensive draperies to relieve them.

For the manufacture of intricate scroll work, fine machinery and accurate workmanship was necessary as well as careful design. In the manufacture of modern casings, columns, etc., universal care is necessary, from the selection of the wood, throughout the processes of manufacture to the finished product. One piece of green wood or a piece off color or grain, will ruin the finest piece of work, for the finished work must stand with its design and construction in the open, where the slightest defect is magnified.

In the manufacture of high class grilles, interior columns, etc., the Chicago Grille Works, 834 Wells street, Chicago, holds a most enviable position. With a record of nearly twenty years in one location, increasing their plant from time to time, they feel justly proud

MODERN CONSTRUCTION.

of their progress. Their intimate knowledge of materials, conditions, and a perfect plant enables them to manufacture the best class of work at slight cost above greatly inferior goods. While they have been disposing of their product through jobbers in the past, it is now possible to buy direct from them, thereby saving time and the middleman's profit. The mention of the National Builder will secure one of their beautiful catalogues, which should be in the hands of every contractor and builder.

"BURMITE QUALITY COUNTS."

Some time past, quite a number of the architects, contractors and property owners considered ready-to-lay roofing simply a material which could be bought for so much a roll and nailed down without any special care. This condition has been changed however. Those who will look over the new book of bungalows, garage and home designs issued by the Bermingham & Seaman Co., Chicago, will awake to the fact that a high grade, ready-to-lay material, such as "Burmite," is much better than the average smooth-surfaced roofing generally found on temporary structures.

The manufacturers of Burmite show and can prove, by many buildings on which their material has been used, that Burmite is suitable for the finest residences, churches, apartment buildings, etc. For instance, in their book of designs is shown a two-story and

attic cottage, the first story being constructed of cement blocks in rock-faced ashlar design. The second story is sided with Burmite "Stoddard" slate-green with panel strips of wood, painted white, and Burmite slate-red for the roof. The effect of this combination of colors makes an extremely artistic appearance, besides being much cheaper and having better lasting qualities than cement, plaster or stucco.

Another good effect is shown in a large three-story, half-timbered summer home. In this Burmite slate-green has been used throughout as siding, panel strips of wood painted white are used to cover joints, and Burmite slate-red is on the roof.

Not only is Burmite being specified by artistic home builders, but it can be used on the interior as a burlap. The slate-green, for instance, can be easily nailed on for the ceiling and siding down to within three feet of the floor, and the balance then covered with the Slate-Red. This would make a very nice combination for a kitchen or dining room, and really make a fireproof wall as well. Panels painted in some good contrasting color would add greatly to the fine appearance of rooms so decorated.

The lasting qualities of Burmite for either exterior or interior work are excellent. Property owners are even using it for porch and veranda flooring and for stair treads.

Burmite consists of a felt base thoroughly saturated with pure asphalt. This is reinforced with strong burlap, carefully protected on both sides by pure asphalt. (The important feature of this roofing is its wearing surface, which consists of Bird Sand and a double layer of Slate Chips, imbedded under great pressure.)

The Slate-Surfaced Material comes in two colors—slate-green and slate-red. As the colors are the natural tints of the slate, they are referred to as non-fading. The manufacturers claim for this ma-

terial, which is shipped in rolls with nails, lap cement, etc., for laying, that it requires no painting, remains uniform in color, is a perfect fire-retardent, hail-proof, and impervious to moisture. It is said that it requires no expert labor in laying, and that on roofs of any degree of pitch it meets every condition involving rain, snow, sleet, sparks, sliding ice and sudden changes of temperature. It is guaranteed for ten years without painting or coating.

As a material for grain elevators, it is far superior to corrugated iron in many ways. It is said that dampness from the grain causes the iron siding to rust from the inside and that grain elevators sided with Burmite do away with this objection and makes as fireproof a building at a much less cost.

The Bermingham & Seaman Co., Tribune Bldg., Chicago, offer to send, upon request, their book of bungalow and house designs, which is printed in colors and is a very attractive thing for contractors and builders to show prospective home owners and to specify from. Besides this book, they are mailing samples which clearly show what Burmite is, both as to color and manufacture.

Burmite can be had from local lumber or hardware dealers, but where not carried in stock, a request for it should supply the demand through that dealer within a few days.

Amatite ROOFING

Needs No Painting

MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

With Amatite, nothing of the sort is required. It gives real roof protection *without painting* of any kind.

Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed with Coal Tar Pitch.

Second—Because it has a real mineral surface.

Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and the user saves all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write today for further information and sample. From it you will very quickly understand why it doesn't require painting and why it does not leak.

How to know CORTRIGHT Metal Shingles

Group of Metal Slates

Group of Victoria Shingles

Group of Oriental Shingles

Imperial Shingle

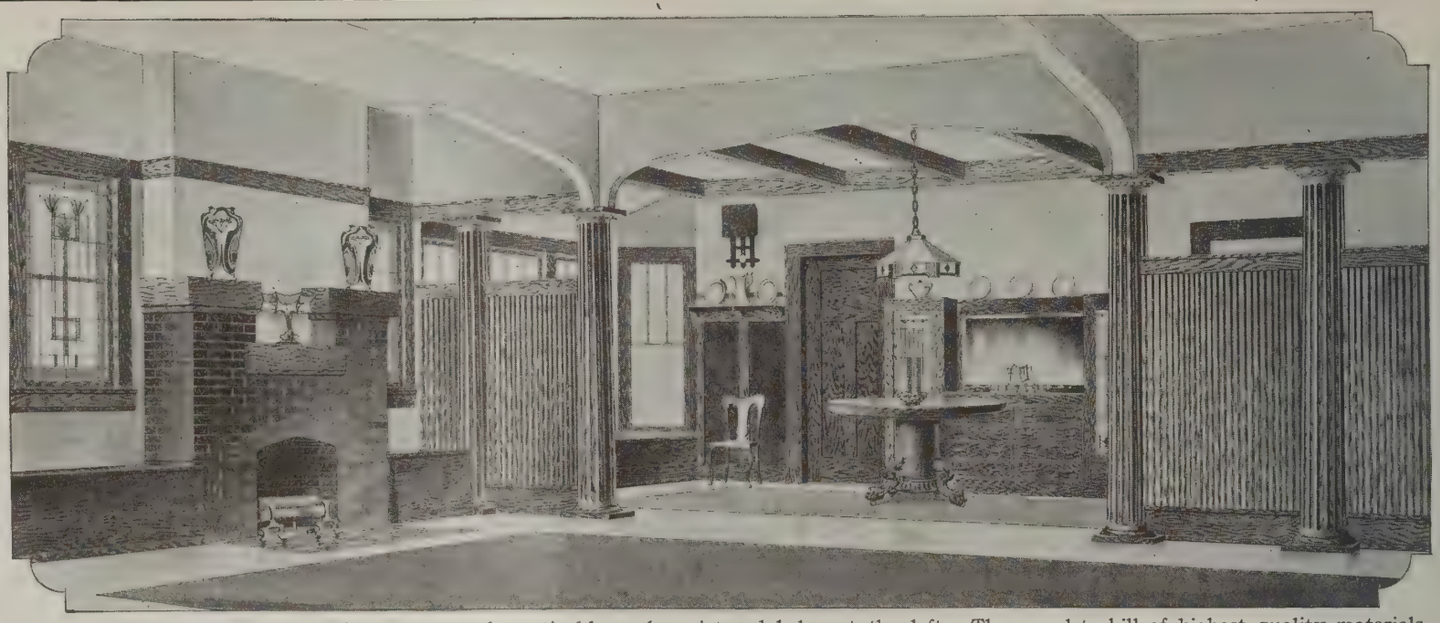
Since Cortright Metal Shingles became so successful 26 years ago, a lot of manufacturers have thought that all they had to do was to make a shingle to look something like Cortrights, and it would be equally successful. But they've failed.

After they sell a man a roof with the argument that it's just as good as "Cortright's" it usually proves so troublesome as to discourage him altogether with metal shingles.

Even some carpenters and builders have been fooled by this "just as good" argument, and it's still a worse investment for them than for the property owner, for if you lay a roof that's only going to be a yearly annoyance to your customer you lose many times your original profit.

That's why it is so important that you should know these four designs, and look for the words

"CORTRIGHT" REG. U.S. PAT. OFF.



which are stamped on the top of each genuine Cortright Shingle. (See where the arrows are pointing.)

And to prevent you from taking any kind of risk, why don't you send for our two free roofing books that you can keep on hand for reference.

Write for them right now before you forget.

The living and dining rooms of the pretty and practical bungalow pictured below at the left. The complete bill of highest quality materials for this bungalow as shown, excepting only the brick, plaster and cement, was purchased from Sears, Roebuck and Co. at a cost of $1,292.00, a complete set of building plans and specifications, for which the average architect would charge $150.00 or more, being supplied without cost.

A charming bungalow, just completed at Greeley, Colo., in the Rocky Mountain country, at a total cost of $2,843.91. The owner, J. P. Berck, estimates that he saved $500.00 by buying all his materials from one firm, Sears, Roebuck and Co., at wholesale prices. (See interior view above.)

This modern home, of which an interior view is shown below, was built complete at New Rochelle, N. Y., "Forty-five minutes from Broadway," at a total cost of $3,960.00, and affords an interesting example of the kind of houses designed and planned by Sears, Roebuck and Co., and of the high grade materials they produce.

A glimpse of the artistic and handsomely finished interior of the seven-room residence shown above at the right, recently erected from plans drawn by Sears, Roebuck and Co., which were supplied free with complete specifications. The same company furnished all lumber, lath, cedar shingles, mill work, beam ceiling, clear cypress siding, oak and maple flooring, finishing lumber, Craftsman doors and buffet, leaded glass, glazed windows, medicine case, building paper, pipe, gutter, sash weights, hardware and painting material for $1,653.00.

Let Us Ship YOU a Modern Home Complete

Have you ever discovered, after exerting yourself to the utmost in the interests of a client and actually losing money on his job through delays for which your supply dealers were to blame, that he was going around warning other intending builders not to patronize you because you failed to keep the cost of his house within your estimate? You guessed wrong.

Why guess? Why not quote a flat price on every job you are asked to figure on, a price that your competitors cannot touch? With our Wholesale Lumber Price List, our Building Material Catalog and our book of plans on your desk you can file your bid the **same day it is asked for** and can **land the job** while your rivals are writing to dealers all over the country to get prices that are sure to be one-third higher than our direct from factory wholesale prices.

There are bigger profits than ever in building modern homes by modern methods if you **buy your materials the modern way.** Adopt the Sears, Roebuck and Co. plan on your next contract. Avail yourself of the almost unlimited resources of our Modern Home Department. Let your client select one of our 100 houses or bungalows, for which we will furnish you, free of cost, complete building plans and specifications. Then, if you know the capacity of your workmen, you can quote your client a flat price for his house instead of estimating its cost by guess. By this plan you can also know in advance just what your profits will be when the job is finished, and can thus spend your profits as the work progresses.

Some of the best informed builders in the contracting business—men who know practically everything about the technical side of home building—fail to get ahead because they are too careless to **buy right** when ordering materials and supplies.

MILL WORK

Modern Art in Home Designing Demands Constantly Higher Standards in Mill Work Manufacture.

In selecting from our own enormous lumber yard the materials from which our mill work is manufactured, we exercise the same care and discrimination as is employed by makers of the most expensive furniture.

The sample prices quoted below are for the best quality goods that can be produced. They afford only a suggestion of the big savings you can accomplish by ordering your mill work and building material from us.

Remember, we sell direct from the factory, at one profit prices, not only every line of material shown on this page, but everything required to build houses of the type illustrated on the opposite page, complete and ready for occupancy. We quote:

Yellow Pine Doors, four-panel	$0.95 up
White Pine Doors	1.40 up
24x28-Inch Check Rail Windows, for two sashes.	1.00 ea.
Window Frames	1.00 up
Door Jambs	.45 up
Quarter Round Molding, per 100 feet	.25

Send us your next list. Let us quote you our Wholesale Price, DELIVERED TO YOUR STATION. Then compare prices. You will find our prices lowest when quality is considered.

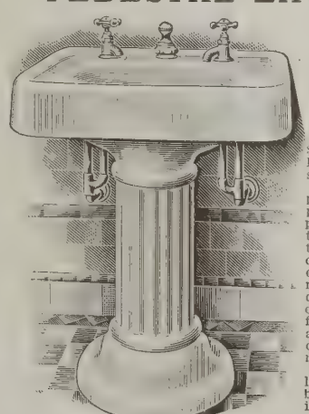
Write for our Mill Work Catalog.

Seroco Ready Mixed HOUSE PAINT

Made in our own modern paint factory, the perfect product of twenty-eight years' practical experience. We buy our own raw materials and are not dependent upon any other paint manufacturers to supply our wants.

$1.10 to $1.23

A Gallon, According to Quantity.



Furnished in All Shades.

We guarantee SEROCO Paint to be composed of the highest grade ingredients; that it is a perfect preservative and contains nothing injurious; will cover 250 to 300 square feet, two coats to each gallon; will not blister, peel, chalk or rub off, and will wear well on buildings. We agree to furnish new paint free, if our Seroco paint fails to come up to our guarantee.

Our Paint and Varnish Catalog quotes our complete line of paints and interior finishes, as well as painters' supplies.

Remember that the big saving we effect for you by selling lumber, mill work and supplies, direct from our factories at one profit, constitutes only half the advantages our plan affords you. Consider the time and the disappointments you can avoid by ordering from one firm ALL the materials you need to build and finish a high class and artistic home. No frantic telegraphing to dealers, who may not be at home to receive your messages, about delayed shipments. Instead, a follow up clerk is working for you in our house, always on the job, following your order through every department to make sure that each shipment of materials reaches you without delay and in perfect condition.

FIRST QUALITY ENAMELED PEDESTAL LAVATORY.

ONLY $25.00

If you have been paying $45.00 to $65.00 for pedestal lavatories like this one, resolve not to do it any more.

You have only to compare our goods and the prices quoted in our 44-page Plumbing Catalog with those you are familiar with to realize that we save our customers from one-third to one-half on bathroom furniture and plumbing goods of all kinds. All fresh, clean goods, direct from the factory, and strictly guaranteed as to quality and durability of enamel and nickel plate finish.

Clip the coupon in the lower right hand corner and be sure to check the Plumbing Catalog.

(PASTE THIS UP ON YOUR DESK.)

OUR GUARANTEE:

Your money, including any freight charges you may have paid, will be cheerfully returned if you are not perfectly satisfied.

SEARS, ROEBUCK AND CO.

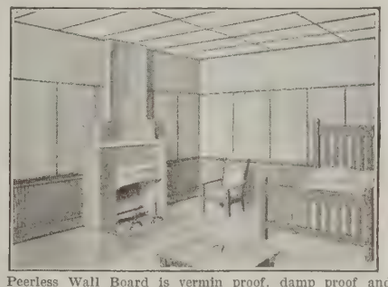
DID YOU READ OUR BIG AD LAST MONTH?

LUMBER

Buy, for What Your Dealer Has to Pay, a Better Grade of Lumber Than He Supplies.

To know how much the best lumber is actually worth, and how much profit you are paying the local dealer, you have only to compare your bills with our Wholesale Delivered Lumber Price List, showing exactly what any bill will cost you delivered at the freight depot in your city. We save you from $100.00 to $150.00 on an average size carload of lumber.

If that last statement be true, can you afford to ignore it? Can you read our guarantee and doubt its truthfulness?



We carry on hand, in our own great lumber yards, adjacent to the finest timber lands in America, a stock of 1,250 carloads (nearly 15,000,000 feet), embracing a full range of sizes for every kind and grade; also a duplicate of this stock at our yards in Southern Illinois. We have exactly what you want in the quantity you want, and it is ready to ship.

Write for our Wholesale Delivered Price List of Lumber. It quotes you prices, including freight charges, DELIVERED TO YOUR STATION.

Let us put your name on our monthly mailing list, which insures your getting our latest prices throughout the year.

Peerless Wall Board

Made of three plies of heavy sanitary fiber board, with two layers of best grade asphalt between, and cemented under heavy hydraulic pressure into one solid fabric.

Peerless Wall Board is vermin proof, damp proof and sound proof; retains heat and excludes cold better than any other plaster board made. Will not crack or warp. Can be tinted and frescoed or papered if desired, and can be applied by an unskilled workman in one-third the time required for ordinary plaster. Sized ready for use and finished a rich brown on the exposed side.

Our Prices on Peerless Wall Board Save You One-Half.

Sheets are 3-16 inch thick, 32 inches wide, and are furnished in 8, 9, 10, 11 and 12-foot lengths.

Price, per square foot, in lots of 500 square feet or more..... 2¼c

Smaller quantities at proportionately low prices.

SAVE $50.00 ON THE AVERAGE SIZE ROOF.

Let us send you a complete layout of roofing samples as well as our Roofing Catalog. Every price in this Roofing Catalog shows a saving of 25 to 50 per cent over the average dealer's prices.

TARRED FELT ROOFING. Best quality, 108 square feet, 75-cent value.
Price, per roll..... $0.50

RUBBER ASPHALT ROOFING. The ordinary kind, 108 square feet, $1.25 value. Weight, 34 pounds.
Price, per roll..... $0.79

FLINT COATED RUBBER ROOFING. 108 square feet, $1.65 value. Weight, 50 pounds.
Price, per roll..... $0.95

These Pocket Knives Stand Hard Usage

A man's pocket knife is his constant companion. There is hardly a day in the year when he doesn't use it, to whittle, or pry, or dig—*on* something or *at* something—because it's the *first* thing, or the *only* thing, that comes handy to work with.

So—it follows that a pocket knife should be *good* or else it's "no good."

KEEN KUTTER

Pocket Knives

are the kind that "take hard usage." Of course, you could break one, because a knife isn't a crowbar, but fact is, any kind of *ordinary* use you'll put a Keen Kutter Pocket Knife to, won't "faze" it at all.

Keen Kutter Pocket Knives have hand forged blades of finest tool steel, and perfect temper. Springs that are *springy*. Rivets that hold firm. Handles that feel right in the hand and edges that cut smooth and true, and stay in cutting trim so long as to surprise you.

Every Keen Kutter Pocket Knife is guaranteed. There is a size and style for every man and boy. Get yours to-day.

TWO PRACTICAL BOOKS

PRACTICAL BRICKLAYING—SELF-TAUGHT. BY Fred T. Hodgson, F. A. I. C. 277 Pages, 300 Illustrations, 12 mo, Cloth Binding. Price.....**$1.00**

Bricklaying is becoming quite an art, and the "bricklayer" is becoming of as much importance today as he was in the 16th and 17th centuries. It is absolutely necessary now-a-days that, in order to take his proper place among the arts and crafts, he become familiar with all the minutiae of the trades. As much art can be displayed in brickwork as in any other of the trades, and it is up to the working bricklayer to get all the knowledge possible regarding his calling, so as to enable him to execute any kind of work relating to his trade. This book is designed to help him out in this matter, and discusses the various kinds of bond, ornamental brickwork, damp courses, quality of brickwork, forming of pilasters, quoins, skew arches, splay work, brick joints, chimneys, fireplaces, flues, brick-pavings, and many other classes of brickwork. The work contains 300 fine illustrations.

PRACTICAL STONEMASONRY—SELF TAUGHT. By Fred T. Hodgson, F. A. I. C. 300 Pages, 500 Illustrations, 12mo, Cloth Binding. Price.....**$1.00**

This book deals with stone cutting and mason's work, methods of building walls in rustic rubble, ashler square, uncoursed, random coursed, irregular corners, snecked and square rubble polygonal ragwork, and other styles of masonry and stone cutting are explained and illustrated. Finished stones, such as window sills, window heads, coping, arch stones, key stones, and similar dressings are described and illustrated. Stone arches and joints are described and illustrated, with ample instructions for working them.

The book contains hundreds of illustrations and diagrams, and is a complete cyclopedia of practical instructions in masonry and must prove of inestimable value to the operative mason.

THE GREATEST WORK
ever published on Architecture, Carpentry, Contracting, Building and all allied branches is the new 10 volume edition

Cyclopedia of
Architecture, Carpentry & Building

Ten massive volumes; 4,670 7x10 inch pages; 3,000 full-page plates, detail drawings, plans, color plates and photos of buildings completed and in course of construction. Bound in half morocco leather and printed on special enameled paper in large, clear, readable type. Titles beautifully engraved and stamped in 23 carat gold.

No work so comprehensive, so authoritative, has ever before been placed on the market. This great work is a complete review of architecture, carpentry and building. Every problem likely to confront you in your daily work is solved and the solution placed before you in such a clear manner that you cannot fail to understand and profit by it.

Just examine the "Partial List of Contents" below and you will at once realize how broad is the scope of this work—how thoroughly it covers the building trades.

PARTIAL LIST OF CONTENTS

Reinforced Concrete—Contracts and Specifications—Building Materials—Carpentry—Building Superintendence—Estimating—The Law of Contracts and Liens—Masonry—Stair Building—Heating—Ventilation—Hardware—Steel Construction—Elevators—Architectural Drawing—Freehand Drawing—Blue Printing—Greek and Roman Orders—Water Color Hints for Draftsmen—Painting—Wiring of Door Bells—Sheet Metal Pattern Drafting—Mechanical Drawing—Lettering—Shades and Shadows—Rendering in Pen, Ink and Wash, etc.

READ OUR LIBERAL OFFER
THEN SEND THE COUPON

To prove our absolute confidence in the superiority of this work over all others, we make this liberal offer: Upon receipt of the coupon in the lower right hand corner, we will place the entire cyclopedia of ten volumes in your home or office—you keep the books five days—examine them thoroughly, critically—subject every formula and problem to a severe test. If you are satisfied, send $2.80 after examination and $2.00 every month until you have paid the special $24.80 price. The regular list price is $50.00. As a further guarantee, we will remove the books at our expense if you are not satisfied. We pay all express charges.

The books are compiled from the instruction papers of the American School of Correspondence. If you are interested in our Building Courses, mail the Coupon at the left. It will bring full information and valuable advice by mail at once.

The Kind of Saws Mechanics Want

The complete line of SILVER STEEL SAWS contains over twenty-five different patterns—all made in a range of lengths from 18 inches up and in all points from 4½ to 12.

We have selected four of the most popular patterns, which we wish to show you this month.

This is No. 53. The Blade is of SILVER STEEL, Damaskeened finish, Skew Back. The Perfection Pattern Handle is of thoroughly seasoned, applewood, beautifully carved and finished. It retails from $1.60 to $2.50 each according to size.

This is ATKINS No. 51 with old style straight across handle. The Blade is of SILVER STEEL, Damaskeened finish, Skew Back. The Handle is of thoroughly seasoned applewood. This Saw sells from $1.45 to $2.15 according to length.

This is ATKINS No. 68 and one of the finest Saws we make. The Blade is of SILVER STEEL and is given our highest mirror polish. Skew Back. Carved and polished applewood handle, Perfection Pattern. This Saw sells from $1.65 to $2.50 according to size.

Here is ATKINS No. 66, SILVER STEEL, high mirror polish, Skew Back, apple handle, old style straight across pattern. This is a strictly high class Saw and retails from $1.60 to $2.25 according to length.

THE HANDLES

We want to call your particular attention to the difference in the hang of these two handles. Nos. 53 and 68 have the Improved Scientific Perfection Handle. Easiest on the saw arm. Nos. 51 and 66, the old style straight across handle if you prefer it.

ATKINS ALWAYS AHEAD!

Send for our Saw Sense Book or Carpenters Catalog which will tell you about the complete line. It's free upon request. Or send us ten cents to pay postage and we will send you with our compliments a substantial nail apron, our little book called "Saw Sense," a monthly time book and other useful information in regard to High Grade Saws.

YOUR DEALER SELLS THEM or will order them for you from his wholesale house. If he won't supply you, let us know. Buy one and try it. If it does not run easier, cut faster and hold its edge longer than any other Saw—if it is not more satisfactory than any saw you have ever used before—take it back to your dealer and get your money back or exchange it for a new one.

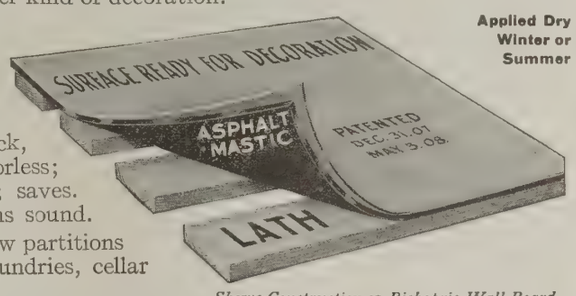
BISHOPRIC WALL BOARD AND SHEATHING

BISHOPRIC Wall Board is cheaper and better than lath and plaster. It is the ONLY Wall Board COMBINED WITH LATHS and Asphalt Mastic. Laths are necessary in a Wall Board, just as they are in plaster walls, to prevent warping and to insure solid, rigid, stiff substantial

WALLS AND CEILINGS



Bishopric Wall Board Easily Applied

Bishopric Wall Board also is the only Wall Board with a water-proof body. The Asphalt Mastic in which the laths are imbedded affords absolute protection against dampness. Does away with delays in building. Applied winter or summer. Is nailed to studding dry, ready for immediate application of paper, paint, burlap or any other kind of decoration.

Bishopric Wall Board is made of kiln-dried, dressed laths imbedded in hot Asphalt Mastic, surfaced with sized cardboard and cut in the factory into 4x4 ft. sheets. Shipped in crates ready for immediate nailing to studs. It is guaranteed not to swell, shrink, warp, crack, flake or blister. It is clean, sanitary and odorless; proof against moisture, cold, heat and vermin; saves fuel and keeps out summer heat; also deadens sound.

It is suitable for dwellings, factories, new partitions in old buildings, finishing attics, porches, laundries, cellar ceilings, garages, etc.

Applied Dry Winter or Summer

Shows Construction of Bishopric Wall Board.

PRICE WALL BOARD AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6.40 per crate, or $2.50 per 100 square feet, f. o. b. New Orleans, La., Cincinnati, or Alma, Mich. We ship from nearest point.

T. W. Hanes, Carpenter and Contractor, Mounds, Ill., wrote August 15: "I have used 13 crates of Bishopric Wall Board, and the waste could be put in a hat."

Wm. Cooper, Taxidermist, Milo, Me., March 9, wrote the Philadelphia Farm Journal: "Your interesting paper has been a real bonanza to me. I wanted a cheap, warm method of lining my new work room. An advertisement in your paper gave me the very idea and material at a price that suited my pocket. I wrote to two firms who advertised with you, but selected 15,000 ft. of sheathing from the Bishopric Wall Board Mfg. Co. of Cincinnati. If the stuff was made on purpose, it could not suit me better; and a most prompt, obliging firm they are, too."

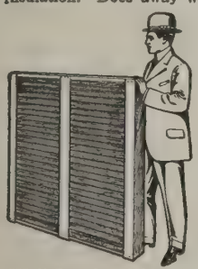
Cheaper Than Lumber. Saves 75% on Labor. Does away with Building Paper.

BISHOPRIC SHEATHING

Ideal Material for Cement Buildings or Stucco Exteriors. Proof against Dampness.

Bishopric Sheathing is made of same materials as Wall Board, but finish is not necessarily so fine, therefore costs less. It is of uniform thickness, insuring a perfectly even surface when applied.

Bishopric Sheathing is nailed to studs, with lath and asphalt side exposed. Over laths, weather boards are nailed or cement applied.



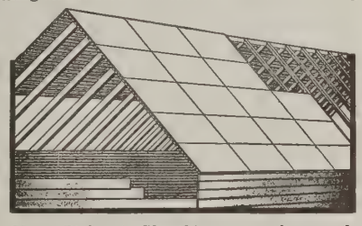
Shows construction of Bishopric Sheathing.

Arrow points to Asphalt Mastic into which laths are imbedded.

Bishopric Sheathing makes a more solid and substantial wall than lumber. There are no gaping joints; no widening cracks due to shrinkage; no knot holes.

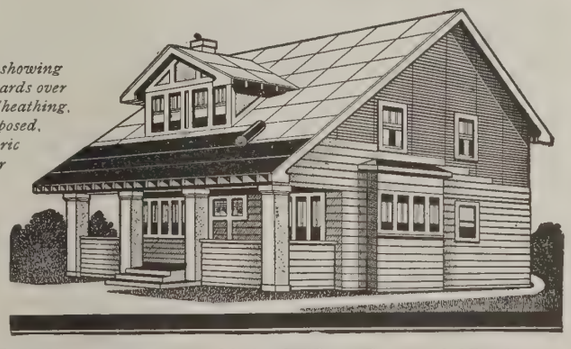
The Asphalt Mastic in Bishopric Sheathing is a non-conductor, moisture cannot penetrate it. It is proof against vermin. The pests cannot bore through the tough, gummy Asphalt Mastic. In applying weather-boards over the laths, dead air space is left between the laths forming splendid insulation. Does away with the expense of building paper and cost of its application.

Wall Board and Sheathing are shipped in crates



The cost of applying Bishopric Sheathing is but $2.50 per 1000 feet—A SAVING OF ABOUT 75 PER CENT. Furthermore, 1,000 square feet of wood sheathing covers but 750 feet of surface, 20% less being due to tongue and groove. In Bishopric Sheathing 1,000 square feet covers 1,000 square feet of space

Bishopric Sheathing insures comfort during the construction of the building. As soon as the building is closed in with Bishopric Sheathing, the men may work in comfort on the inside during bad weather, finishing the outside on suitable days. This insures continuous work, without loss of time, enabling the contractor to hold his men and complete the work in the least possible time.



Bishopric Sheathing is used with equally splendid results under flooring and as a substitute for roofing boards. Used under floors, it serves as a sound deadener and keeps out dampness; used under the shingles, it keeps out summer heat.

ITS MANY USES—Bishopric Sheathing also is used with excellent results as a lining for dairy barns, ranch houses, poultry houses, driving stables or any out-door building where protection from the elements, Summer or Winter is desired.

Bishopric Sheathing is the ideal material for cement exterior or stucco work. Cement firmly adheres to the laths and Asphalt Mastic and makes a solid, smooth exterior. For factory or residence this form of cement or stucco construction is the cheapest and best known.

Shows Bishopric Sheathing over rafters ready for Bishopric Roofing, also Weather-boards over Bishopric Sheathing.

Ideal home showing Weather-boards over Bishopric Sheathing, lath side exposed, also Bishopric Roofing over Bishopric Sheathing, (smooth side of sheathing exposed)

PRICE SHEATHING AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6, or $2.35 per square of 100 square feet, f. o. b. New Orleans, La., Cincinnati or Alma, Mich. We ship from nearest point.

Write for Descriptive Booklet and Samples of Bishopric Wall Board, Bishopric Sheathing and Bishopric Roofing—All will be sent free.

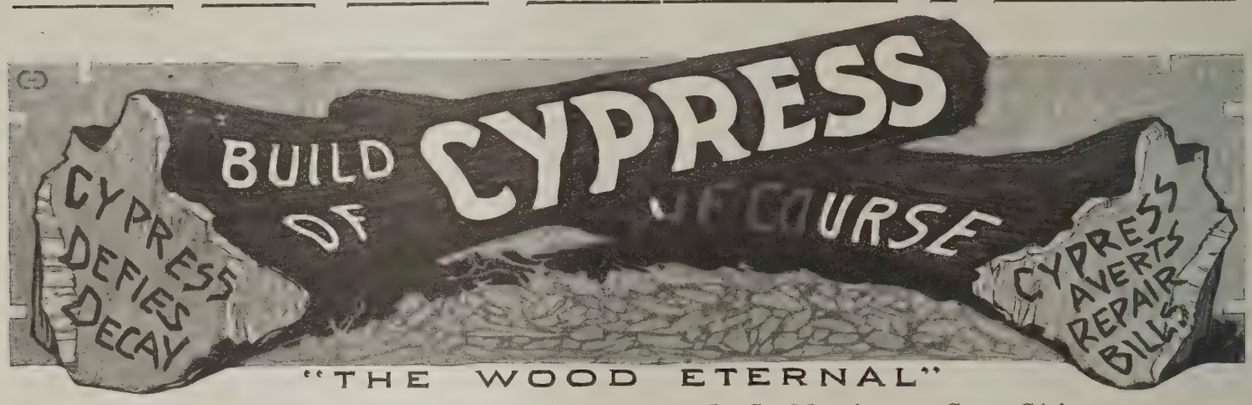
NOTE—Wise, up-to-date **Contractors** and **Builders make a hit** with their best customers by **Recommending Cypress, "The Wood Eternal." Do you?**

CAN YOU THINK OF ANY HARDER TEST FOR WOOD THAN GREENHOUSE USE?

You know ordinary wood in greenhouses lasts *not over 4 years*



Zero on one side, hot humidity on the other, constant contact with wet rich earth and compost, constant sprinkling and sweating, all combine in *an invitation to hurry up and rot.*

NEXT TO THE GROWTH OF THE PLANTS THEMSELVES

THE BUSIEST THING IN A GREENHOUSE

is the decay-tendency of the wood it is mostly made of.

THOSE WHO MAKE GREENHOUSES A BUSINESS

"THE WOOD ETERNAL"

One of the largest greenhouse manufacturers, J. C. Moninger Co., Chicago, says: "We first began using Cypress *exclusively* for greenhouse construction in 1885, using it previously in conjunction with pine. The greenhouses then built with Cypress *are being used today* by their owners and the *wood* is found *perfectly preserved and free of any decay or rot.*" *Figure it out yourself.*

WRITE TODAY for VOLUME 3 of the CYPRESS POCKET LIBRARY, with 20 PAGES of Valuable Guidance for Greenhouse Contractors. (SENT PROMPTLY and no charge.)

"WOOD THAT WILL STAND THE GREENHOUSE TEST WILL STAND ANYTHING," SO INSIST ON CYPRESS FOR EVERYTHING.

When planning new improvements or repairs to old ones, just remember—*"With CYPRESS you BUILD but ONCE."*

Let our "ALL-ROUND HELPS DEPARTMENT" help YOU. Our entire resources are at your service with Reliable Counsel.

SOUTHERN CYPRESS MANUFACTURERS' ASSOCIATION
1212 HIBERNIA BANK BUILDING, NEW ORLEANS, LA.

INSIST ON CYPRESS AT YOUR LOCAL DEALER'S. IF HE HASN'T IT, *LET US KNOW IMMEDIATELY*

"The better a builder builds his buildings—or even alterations—the better he builds his own reputation." The better builders all over the country are glad when their customers insist on **Cypress, "The Wood Eternal,"** or permit them to use it. Cypress is best for the owner because it lasts practically forever **without decay.** (And Cypress is easy to work—**Good for Your Tools.**)

"BEST POSSIBLE RESULTS AT THE LEAST COST"

IS WHAT YOU GET WITH

RED GUM

(AMERICA'S FINEST HARDWOOD)

IDEAL FOR INTERIOR TRIM

"It is my experience that RED GUM interior trim gives the best possible results at THE LEAST COST," says Mr. Gustav Stickley, "the father of the Craftsman movement" in America. Mr. Stickley proves his faith by his works.

Here is a glimpse of the rich yet simple elegance characterizing the new "CRAFTSMAN" Residence of Mr. Fred M. Hill, at Great Neck, L. I. (N. Y.). *ALL THE WOODWORK YOU SEE HERE IS* **RED GUM.**

Why should not *YOUR CUSTOMERS* do as well, Mr. Carpenter or Contractor, when they build, or when they remodel? *Don't wait—investigate* **RED GUM** *BEFORE the DEMAND OF YOUR CLIENTS FORCES the ISSUE. LEARN ABOUT GUM BEFORE you NEED it.*

GET A REPUTATION IN YOUR FIELD as

"THE RED GUM AND SAP GUM ENTHUSIAST."

(If you don't, somebody else will—it's the trend of the times—and there's money in it for you.)

RED GUM takes ANY FINISH—smoothly, perfectly *and WITHOUT FADING.*

Natural Finish RED GUM VENEER equals Circassian Walnut—and costs only a fraction as much.

At its present price RED GUM is the most remarkable purchase in the entire hardwood field. INSIST ON IT for *interior trim*, for *carved detail work*, and for *special order furniture.*

Write any of the undersigned for samples, prices, and lists of important buildings of ALL TYPES and of all costs, wherein RED GUM has given years of eminent satisfaction, both practical and artistic.

It is Yours for the Asking

The Acme Floor Scraping Outfit

To Try It for One Week

No "If's" or "Ands" about my offer. It is a straight business proposition and one that I have adopted to make sales. It is impossible for me to send a representative to every contractor interested in a floor scraper, so instead, I send the Acme Floor Scraping Outfit to represent itself.

I allow you to work with the machine for one week and if at the end of that time you are not satisfied with the results and do not consider the Acme Floor Scraping Outfit the best equipment on the market, simply pack it up and ship it back to me at my expense.

Does this sound like an offer that is worthy of your consideration?

Further particulars and catalog on request.

JOSEPH MIOTKE

249 Lake Street - MILWAUKEE, WIS.

Don't Take Our Word For It—Let Us Send You A Sample

TRY Utility Wall Board on just one job—Note how light in weight and how easily handled it is—Yet how stiff and substantial. Try it under the worst possible conditions and note how staunchly it stands up. No other wall board that was ever made is so moisture-proof and at the same time so readily adapted to any style of artistic decoration.

UTILITY WALL BOARD

is made of exceedingly tough, durable fibre. It is more satisfactory than any other substitute for lath and plaster. You can put wall paper over it with perfect safety. A wall or ceiling finished with Utility Board is permanent—there to stay as long as the building stands.

A New Beautifully illustrated book of interiors will give you some valuable ideas. Send for it at once. Also for the Free Sample

Utility Wall Board is sold through dealers in building supplies everywhere

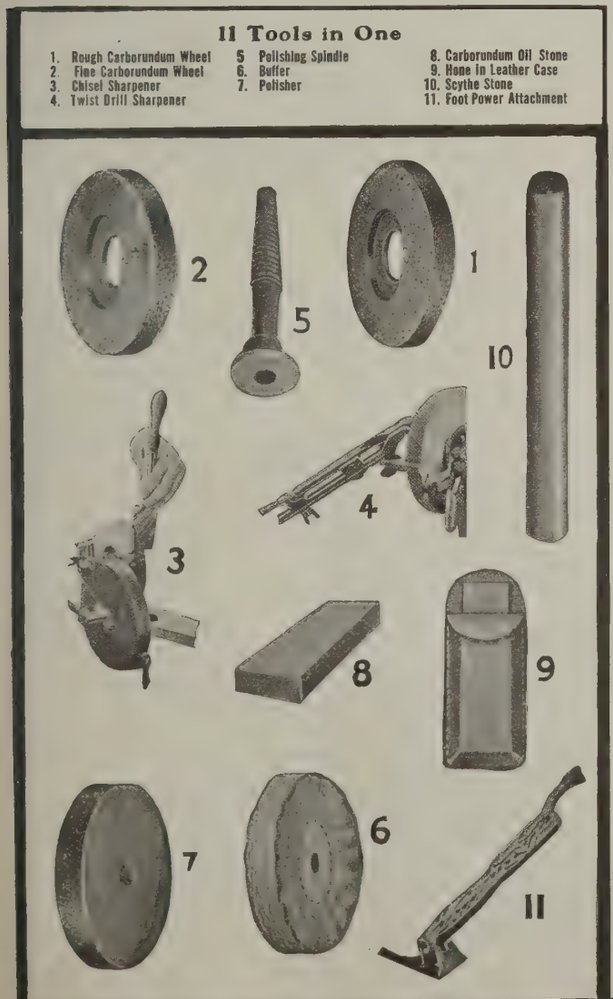
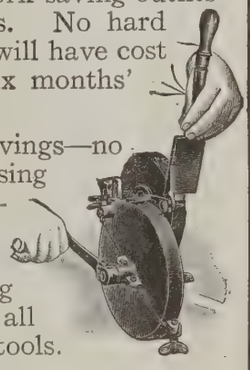
11 Tools in One

25 times faster than Grindstone

6 times faster than Emery wheel





Will not draw temper

Save tools—save time—do all work easier, faster by having your tools always keen. Luther's Mechanic's Special Outfit supplies every sharpening, burnishing and polishing need, makes it the work of only a minute to do the toughest job of sharpening. The outfit consists of the Luther Mechanic's Special Carborundum Grinder with 11 accessories. This is the most complete sharpening, buffing and polishing outfit ever offered, and the most remarkable value.

6 Months' Free Trial

We offer you a whole half year's free trial of this full outfit to prove in your own shop, on your own tools, how this grinder saves and makes money for you—more than pays for itself in the time you use it free. If after a half year's use you do not firmly believe it is one of the greatest time-saving and work-saving outfits you have ever seen—if you do not believe it is a real money-maker for you, return it to us. No hard feelings on our part, and the six months' use will have cost you nothing. Return the coupon for our six months' free trial offer.

Carborundum wheels peel steel away in tiny shavings—no danger of drawing temper—no need of hard pressing—no need of cooling with water. The sharp Carborundum crystals cut toughest steel as emery does copper. Luther Grinders save and make money for any tool user—save money by saving time and tools, make money by making all work easier and faster because of keen, bright tools.

Luther Tool Grinders

are built like high grade lathes—steel and malleable construction, machine cut spur gears, bronze bearings in oil bath, etc. The machine lasts a life-time, and the wheels are guaranteed for 5 years and outlast any number of emery wheels in severest service. This outfit is a very considerable economy for any tool user and we want you to prove it—FREE.

Luther Grinder Mfg. Co., 1808 Madison St., Milwaukee, Wis.

Return This Coupon

Return this coupon for our extraordinary half year's free trial offer on this entire Mechanic's Special Outfit, and for *free* booklet reprinting from McClure's Magazine the story of the discovery of the wonderful artificial diamond abrasive. Cut out the coupon *now*.

A Minneapolis Carpenter Drives 125 Shingle Nails a Minute with a Pearson Nailer when shingling

YOU may not become quite so expert, but Pearson's Nailer will do your shingling quicker, easier and with more comfort than in the old way.

Pearson's Nailer works well on roofs of any pitch or on a level. It weighs about 2 pounds—is very strong—easily handled and drives the nails automatically.

Hit the plunger with the hammer—and the nail is driven down into the roofing about half an inch. Another blow with the hammer on the nail and the nail is clear down.

Just throw the nails in by the handful (the Nailer holds easily between 500 and 600 nails in the top) and start nailing.

You Can Wear Gloves or Mittens When Shingling with a Pearson Nailer

Doing away with all danger of freezing—smashing thumbs or fingers—besides driving much faster than in the old way. The unsanitary way of carrying nails in the mouth is done away with also—and you can smoke while nailing.

Thousands of Carpenters and Contractors are now using Pearson's Nailers—You will be just as well pleased after a trial.

10% DISCOUNT

For 30 days, to introduce the Nailer to new users, we will give a 10% discount. Or instead of $5.00, the price will be $4.50 net. Besides, we will prepay express. Send in your order at once for either the Blue or Red Nailer. The Blue Nailer (painted blue) is for common 3d No. 14 wire nails and the Red Nailer is for the galvanized 3d No. 13 1¼-inch wire nails. Order from your dealer or direct from us, and be sure to state size wanted according to the nail used. Money returned if Nailer is not as represented.

THE PURCHASE OF AN

"AMERICAN"

SAW BENCH

IS A TRUE ECONOMY

The purchase of some machines is a mere extravagance, because they earn nothing. **The purchase of an "AMERICAN" Saw Bench is a true economy, because its use means a saving of time and labor, an improved quality of work, and better business all around.**

Moreover, the "American" Bench is built to be **permanently profitable. It has the qualities which give it lasting power even under hardest service.**

The earning power of an "AMERICAN" Saw Bench does not fall off with long continued use.

An "Amercian" Bench will do all that any saw bench can, with the further great advantage of doing it better, more economically, and over longer periods.

Money placed in an "AMERICAN" Bench is an investment with maximum dividend-paying power.

Taylor Portable Steel Derrick

Tested at factory, hoisted and swung complete circle 1900 lbs. Shipped ready to operate. No wrench or tools required to set derrick on job. Made in two sections. Beam section connects post by tipping in a vertical position and projects at such an angle to clear side wall of building and has sufficient height to hoist wheel-barrows, window frames and timbers. One man can climb a ladder with either section. Consider the durability of a derrick constructed entirely of malleable Iron and Steel and that of Wood, more compact, more powerful.

Derrick complete with three-way block, channel steel brackets, bolts for attaching to building, price $40.00, and four and one-half cents per ft. for crucible steel cable attached. Drum capacity 300 ft.

Special platform and chains for attaching derrick to gondola railroad cars, price $15. Chains for hoisting wheel-barrows, price $2.00.

ARE YOU in doubt, or do you know that there are better things ahead?

Doubt never raised a man's salary—confidence makes many fortunes.

The purpose of the International Correspondence Schools is to give a man confidence in himself by training him in the line of work he prefers. With this equipment he goes to any employer with confidence in his ability to fill the position he seeks.

I. C. S. training is today one of the greatest recommendations that a young man can have. Great employers value it because it is REAL.

A man with I. C. S. training applies to such concerns as Baldwin's Locomotive Works, Cramp's Shipyard, Westinghouse Electric Company, the great Railroad Systems, or any other branch of industry, with the confidence that he will have an opportunity not offered to the untrained man.

Doubt or Confidence

To learn about the I. C. S. it is only necessary to mark and mail the attached coupon. For example, if you desire to become a Civil Engineer you put a cross opposite that occupation. Or, if you desire to become a Mechanical Draftsman, Electrical Engineer, Architect, Advertising Man, Stenographer, Bookkeeper, or fill any other occupation mentioned, you simply mark the position you prefer.

Mark and mail the coupon and the I. C. S. will show you exactly how to accomplish what you desire and will place at your disposal the best industrial training that can be given to any man—young or old.

Mark and Mail the Coupon TODAY

Stanley Tools

"444"

A Combination Dovetail Tongue and Groove Plane

Something entirely new. A Plane that will at one setting cut a dovetail groove, and in the other setting a dovetail tongue to match.

The operation is simple and the accurate and perfect fitting joints obtained, both parallel and tapering, will convince the workman of the utility of this unique and original tool.

A most valuable addition to the kit of pattern makers, cabinet makers, carpenters and wood workers in general.

Send for complete description.

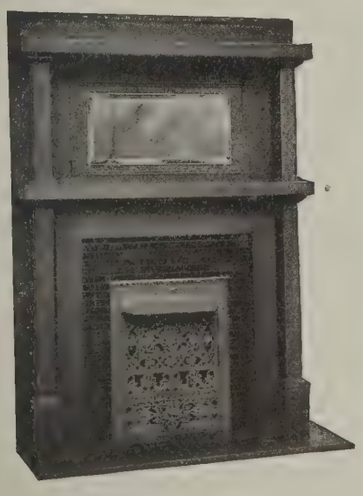
Plant of B. F. Goodrich Co., Akron, O., the largest rubber factory in the world, covered with J-M Asbestos Roofing

Made of indestructible Asbestos (Rock) Fiber and Trinidad Lake Asphalt, the great weather-proofer, J-M Asbestos Ready Roofing is literally a pliable stone. Fire, acids, gases, chemical fumes, heat or cold have no effect upon it. It is therefore practically indestructible

And because of its stone nature, J-M Asbestos Roofing never needs painting or graveling. Its first cost is its only cost. Asbestos being a non-conductor of heat and cold, this roofing keeps a building warm in winter and cool in summer.

Think what a protection J-M Asbestos Roofing is to a building and what it saves in paint and repair bills! It is adapted to any building—anywhere.

We'll sell you J-M Asbestos Roofing direct from our nearest branch if your dealer won't supply you.



Write nearest Branch for Sample and our handsomely illustrated Catalog No. 303.

You Can Pay for the Mixer on a Single Job by the Greater Economy of Operation

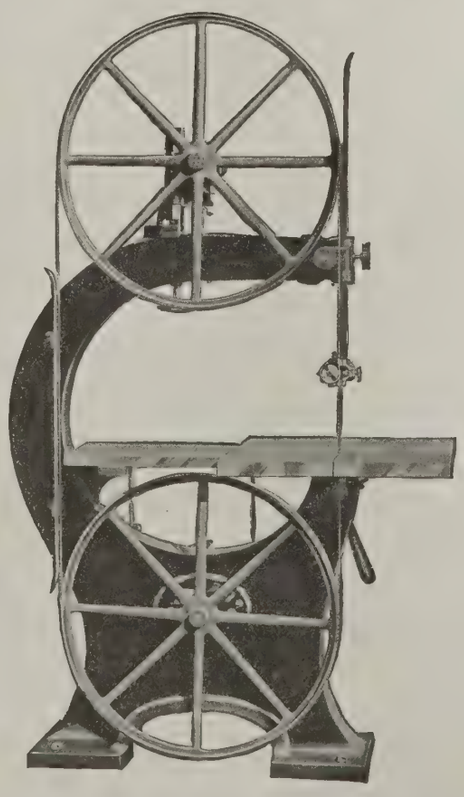
It is not alone the saving of one-third in first cost, one-half in power, one man to operate the hoist and two-thirds the delays and repairs, but the greater portability enabling it to always be kept at the most convenient position on the job for rapid work, that are the distinguishing features of the

Eclipse Concrete Mixer

And we offer our patrons not only greater economy of operation, but unequalled service in shipment. We carry 100 Eclipse Mixers in stock at our factory, stores, warehouses and branch houses for immediate shipment.

It is pre-eminently the mixer for the contractor because it saves money in nearly every possible use.

Our new 1911 catalog No. 32 is just off the press and gives full information how to handle the Eclipse to obtain best results. Write for it. Our testimonial booklet explains how other contractors are making money by using the Eclipse Mixer.



You can buy the small size Eclipse Batch Mixer Complete with Power at a lower price than a Continuous Mixer.

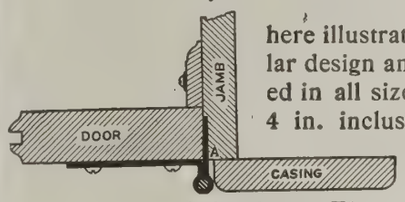
No. 450 —CUT FULL SIZE, 3½ INCH

WE INITIATE—NEVER IMITATE

A Big Hit

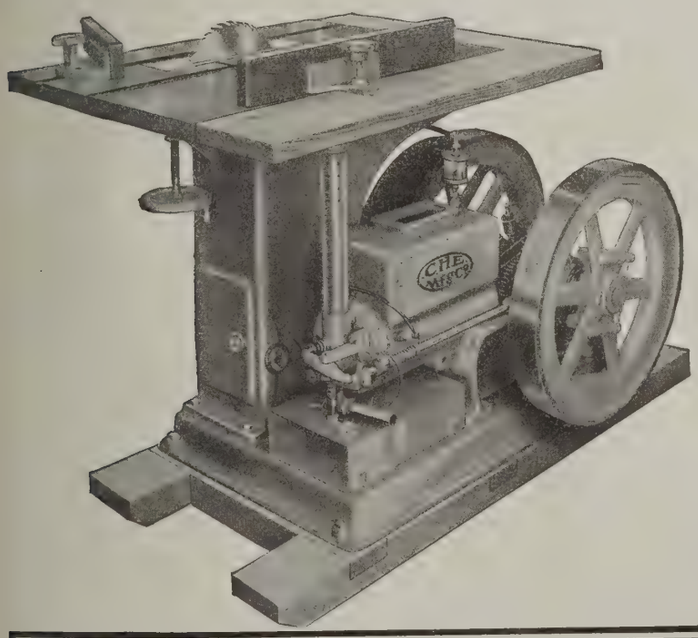
Is the new tip with which "NATIONAL" Butts are now equipped, both Common and Ornamental.



The TIP is threaded and screws into the Butt in both the Japanned and Plated finishes.

It is also SLOTTED for A SCREW DRIVER, making it easy to remove the tip and affords ready access to the pin.

The slot also indicates instantly which is the bottom of the butt—a feature greatly appreciated by the carpenter.



These are exclusive "NATIONAL" features.

Style No. 450

here illustrated is a very popular design and can be furnished in all sizes from 1½ in. to 4 in. inclusive. These butts are highly polished, double plated and have beveled edges. They match escutcheon plates with beveled edges. Ask for "Catalog B" and give dealer's name.

The Power to Grow

Have You Got It?

The man who starts to make concrete blocks with an Ideal Block Machine usually begins to grow from the work "go."

His product is absolutely perfect—true in its proportions, accurate in alignment, sharp cornered and perfect—the kind of blocks the architect, contractor and builder wants.

When increased capacity is needed, there is no necessity to replace the old machinery with new. Using the same block machine with which he started, there are in the Ideal Line numerous time and labor saving attachments with which to attain the desired increase in output, reduce the proportionate manufacturing cost and multiply profits.

No matter how big your business grows

Ideal Concrete Machinery

Will take care of it perfectly

The Ideal is the one block machine that is never outgrown

The Ideal Automatic Power Tamper—for instance, attached to the **Ideal Block Machine** doubles output and cuts down cost. **The Ideal Scraper & Finisher Attachment** automatically insures smooth backed, sharp cornered, perfect blocks. Other big capacity increasers are the Ideal Core Actuator, Ideal Material Conveyors, Ideal Gravel Graders, and the Ideal Continuous Proportioning Mixer. We also equip plants in any unit or capacity desired, for either high pressure or low pressure steam curing or air curing.

Use the coupon to ask for particulars on any of these machines in which you are interested. Or ask us any questions that are in your mind as to the adaptability of Ideal Machinery for your work.

CARBORUNDUM Sharpening Stones

You Can Tell a Good Workman By the Condition of His Tools

That is why so many **GOOD** carpenters use **Carborundum Sharpening Stones**—the stones that keep all edge tools keen and smooth cutting; that never become "slicked" over. **Carborundum Stones** are distinctly different; they cut the steel quickly and easily, leaving a fine, fast-working edge. Other stones merely rub. For general bench tools, the **Carborundum Round Combination Stone** is most practical and convenient; the shape allows for the rotary motion required in sharpening chisels, plane bits, etc.; for tools requiring an extra fine edge, there is the extra hard, extra fine stone. A bottle of **Carborundum Temperoil** will complete the outfit nicely.

No. 107.	Round Combination Stone	$1.00

"The latest invention, and without comparison the most practical, up-to-date woodworker made."

Buffalo Crain Combination Woodworker

Note the ample size and capacity of the parts which perform the four vital operations in your shop: **1. Lathe**—40″ between centers; **2. Band Saw**—taking 12″ under the guide; **3. Saw Mandrel**—taking saw sup to 12″ dia.; **4. Planer Head**—taking 5″ or 10″ bits. The convenient location, strength, simplicity and easy adjustment of these vital parts, are of the greatest advantage. Drilling, boring, sizing, jointing, moulding work, tenoning and, in short, practically every operation of daily occurrence in a woodworking shop, can be performed on it **without extra attachments.** As an investment, it is a true gold mine. **Three men can work at it at one time.** Lowest power cost. Announcement of Awards In Cash Prize Contest

IN the April issue of this publication we offered $150.00 in cash prizes to those giving us the best reasons why they use and recommend Johnson's Wood Dye and Johnson's Under-lac. There were forty-one prizes: First prize, $25.00; five second prizes of $10.00 each; ten third prizes of $5.00, and twenty-five fourth prizes of $1.00 each. The answers had to be in by June 15th, 1911.

The scores of replies received show to what an extent Johnson's Wood Dye and Johnson's Under-lac are depended on by men who look upon every job they do as a standing advertisement and part of their reputation.

Johnson's Wood Dye

is recommended by these men and thousands of others because it is more than an ordinary stain. It is a genuine deep-seated dye that penetrates the wood, giving a rich, permanent color without raising the grain in the slightest. It is easiest to work with, too, and most economical, because it goes farther than any other coloring. It is made in 15 artistic shades, and by lightening or darkening, or blending certain colors, over a hundred beautiful effects can be obtained.

Johnson's Under-lac

is the choice of careful painters and finishers because it is far superior to any varnish, both in results and working qualities. It is not thick and sticky like varnish, is much more easily applied, and dries in half an hour. Better than any kind of shellac, and easier to work with.

Let the Prize Winners Tell You

If you had before you the stack of letters we received in this contest you could hold no further doubts of the *advantage to you* of using nothing but Johnson's Finishes in your work.

The two letters we have space to print here will give you the facts from your own point of view—from the standpoint of the man who does the work and must abide by the results. Read these letters, then if you have not tried Johnson's Wood Dye and Johnson's Under-lac

Send for Free Samples and Prove Their Worth Yourself

We want you to know the superior merits of these Johnson's Finishes. We want you to know, at our expense, that with them you can do better work with less labor. Send us your name and address and name of dealer from whom you purchase supplies. We will see that you get, *free*, and without obligation, samples of Johnson's Wood Dye and Johnson's Under-lac. Also ask for copy of our free book—"Specifications and Instructions for Finishing New Woodwork and Floors"—Edition No. N. B. 9. Address

H. R. BRUNELL Hoboken New Jersey
Wins First Prize

To Mr. Brunell was awarded the First Prize of $25.00 for his direct reasons for using and specifying Johnson's Wood Dye and Under-lac. We give below the reasons and some experiences with these finishes which Mr. Brunell sent us at the same time:

Gentlemen: I will give you a few experiences with your Dye and Under-lac. I am foreman for a New York firm, and have used your Dyes for the past five years. I used your No. 129 Dark Mahogany on Mr. Walker's house in Montclair. He is an architect and has one of the finest constructed houses there. This winter we did quite a large job in the Greenwich Bank Building at 35th Street, corner 6th Avenue, the offices of The American Undergarment Co. We have landed two jobs on account of them. I think without a doubt these offices are the finest in New York City. I could write you a score of such places where we used your Dyes. Three years ago at the Chapter House in Hoboken and Scottish Rites Temple, Jersey City.

I will now give you my reasons for specifying your Dyes from a mechanic's point of view: I find your dyes are easily applied, there is no sediment to them and mix well together, when so needed. But the beauty of them is this: They have such a rich, clean color, give the depth, bring out the figure and all the details of the wood, do not raise the grain and can make a perfect job with either your Wax or Under-lac.

Your Under-lac I like for these reasons: It works freely, does not run, dries very hard over night, gives a first-class effect of rubbing, and is very easily kept clean, just give a light rub with cheese cloth. Your Dyes and Under-lac are both very durable.

A Second Prize Winner

Mr. Stanley Sivers, 606 3rd St., Albany, N. Y., has been awarded a $10.00 prize for the following:

My reasons for recommending your Under-lac are: 1st.—For its good body. 2nd.—Amount of surface it will cover. 3rd.—Does not mar or chip. 4th.—Will not raise grain of wood. 5th.—Good drying. 6th.—Better than shellac.

My reasons for recommending your Wood Dye are: 1st.—For richness of color. 2nd.—Penetrating the hardest wood. 3rd.—For not raising the grain of the wood. 4th.—Will not mar or scratch. 5th.—Is transparent and does not cloud. 6th.—For long service. 7th.—Can produce better work. 8th.—Because I can satisfy people who know what they want and are willing to pay for it.

Other winners of Second Prizes, getting $10.00 each, are:

Mr. F. P. Connolly, 151 S. Water St., York, Pa.
Mr. F. B. Carter, Portland, Oregon.
Mr. Albert Borchardt, Monticello, Arkansas.
Mr. H. W. Richards, 164 Oak St., Elgin, Illinois.

List of Third Prize Winners

$5.00 awarded to each:

C. T. Sullivan, 46 Stewart St., Fall River, Mass.
T. A. Cooper 308 McClellan St., Schenectady, N. Y.
Joseph Denno, Alpena, Mich.
R. F. Flannery, 325 Poole Ave., Long Branch, N. J.

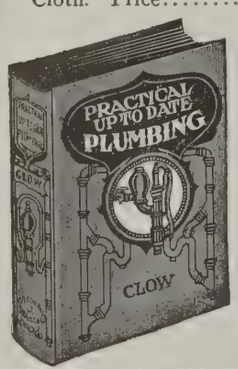
TRADE SCHOOL SERIES

THE RED BOOK SERIES OF TRADE SCHOOL MANUALS, by F. Maire, Director of the Chicago School of Painting, Decorating and Paperhanging

6 volumes, 16mo, Full Cloth. Each Illustrated. Price each.....**$0.60**

The author being acquainted with many of the European and nearly all of the American Manual Training Schools, where painting is taught, feeling the need of a treatise which would help the student or instructors in imparting knowledge, has prepared the following manuals:

(1) Exterior Painting, Wood, Iron and Brick.
(2) Interior Painting, Water and Oil Colors.
(3) Colors, What They Are and What to expect From Them.
(4) Graining and Marbling.
(5) Carriage Painting.
(6) The Wood Finisher.



The arrangement of the above volumes is such that the student is gradually advanced upon the branches treated and the questions at the end of each lesson will become an index of reference which he will find useful. Instructors will surely welcome these valuable manuals, as they will save them numberless repetitions. The student who cannot leave home to attend a school will find his task of learning the various branches treated greatly facilitated by procuring these volumes.

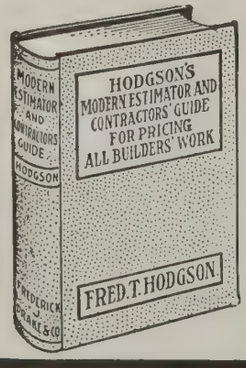
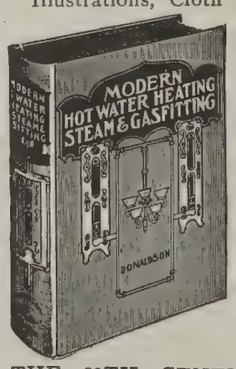
HODGSON BOOK CO. 358 Dearborn Street, CHICAGO



USEFUL BOOKS FOR CONTRACTORS

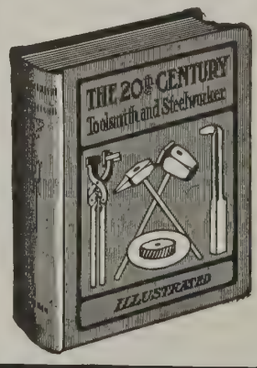
PRACTICAL UP-TO-DATE PLUMBING. By George B. Clow. 310 Pages, Over 250 Illustrations, Large 12mo, Cloth. Price.....**$1.50**



A practical, up-to-date work on Sanitary Plumbing, comprising useful information on the wiping and soldering of lead pipe joints and the installation of hot and cold water and drainage systems into modern residences. Including the gravity tank supply and cylinder and tank system of water heating and the pressure cylinder system of water heating. Connections for bath tub. Connections for water closet. Connections for laundry tubs. Connections for wash-bowl or lavatory. A modern bath room. Bath tubs. Lavatories. Closets. Urinals. Laundry tubs. Shower bath. Toilet room in office buildings. Sinks. Faucets. Bibb-cocks. Soil-pipe fittings. Drainage fittings. Plumber's tool kit, etc., etc. The composition and properties of solder and how to make it, are carefully treated and a chapter is devoted to useful information. There are given a large number of valuable tables giving the pressure at different elevations, capacity of pipes, etc. The work also contains over fifty carefully prepared drawings, giving complete piping connections for home, tenement and office buildings.

MODERN ESTIMATOR AND CONTRACTOR'S GUIDE. FOR PRICING ALL BUILDERS' WORK—WITH MANY TABLES, RULES AND USEFUL MEMORANDA. By Fred T. Hodgson, F. A. I. C. 318 Pages, 100 Illustrations, 12mo, Cloth. Price.....**$1.50**

One of the most desirable books for the general builder to have, is a good and reliable work on estimating; and we are certain the book we are now offering, if the large number of favorable testimonials and press notices we have received is any indication, is one of the best, and most reliable books on the subject that has ever been published on this continent—or any other for that matter. We have no hesitation whatever in recommending this book to our patrons who want a good work on estimating. The work gives a lengthy and clear explanation of the several methods employed in estimating, among which may be mentioned, "Estimating by comparison," "Estimating by the cubic foot," "Estimating by quantities," "Estimating in detail," and several other systems.



HOT WATER HEATING, STEAM AND GAS FITTING. By Wm. Donaldson. Large 12mo, 250 Pages, Over 100 Illustrations, Cloth Binding. Price.....**$1.50**

A modern treatise on Hot Water, Steam and furnace Heating and Steam and Gas Fitting, which is intended for the use and information of the owners of buildings and the mechanics who install the heating plants in them. It gives full and concise information with regard to steam boilers and water heaters and furnaces, pipe systems for steam and hot water-plants, radiation, radiator valves and connections, systems of radiation, heating surfaces, pipe and pipe fittings, damper regulators, fitters' tools, heating surface of pipes, installing a heating plant and specifications. Plans and elevations of steam and hot water heating plants are shown and all other subjects in the book are fully illustrated.

The closing chapter, devoted to useful kinks, contains information on a variety of subjects which will be found of interest and value to the workman, as will also the many useful tables given at the end of the volume.

THE 20TH CENTURY TOOLSMITH AND STEEL-WORKER. By H. Holford. 240 Pages, 120 Illustrations, 12mo, Cloth Binding. Price.....**$1.50**

This book is written in the interests of all mechanics connected with the working and manufacture of steel into tools, and gives all the secrets and obstacles to be overcome towards making steelwork or toolmaking a success. It will be invaluable to the young mechanic and place him years in advance of his fellow workman, by the reading and a little reflection of its contents.

It is not comprised of quack theories or foolish ideas, and is not written by a college student, who knows nothing except what he has been told or gathered up from papers and periodicals. But is written by a thorough expert mechanic who has spent the best part of his life over the anvil with the hammer and tongs.

WILLIS MFG. CO.

GALESBURG, ILL.

Manufacturers of the

Famous Willis Skylights and Ventilators

All "asphalt roofing" is not Trinidad Lake Asphalt Roofing—there's a great big difference. Look out for that when you buy your roofing.

Ordinary so-called asphalt roofings are made of artificial products masquerading as real asphalt, They are nothing more than the residue from petroleum oil or native bitumens made into a black pitch, which is easily affected by changes in weather.

Genasco

the Trinidad-Lake-Asphalt Roofing

it made of genuine *natural* asphalt—perfectly stable and uniform in quality.

Trinidad Lake Asphalt is endowed by Nature with *natural* oils; and they stay in it. This gives Genasco its wonderful resistance to rain, snow, sun, wind, heat, and cold—and keeps it lastingly waterproof.

The artificial asphalts have oils *mixed* with them, but they haven't the quality of the oils in the natural product; and they soon evaporate and leave the roofing "dead"—and it cracks, breaks and leaks, although at the first it may look like Genasco, the real Trinidad-Lake-Asphalt roofing.

Natural asphalt in roofing is the greatest weather-resister known. To make sure of roofing that will permanently protect, ask your dealer for Genasco, the Trinidad-Lake-Asphalt Roofing, with either mineral or smooth surface. Fully guaranteed.

The Kant-leak Kleet waterproofs the seams of Genasco Roofing without cement, does away with nail-leaks, and gives the roof an attractive finish. Ask your dealer for Genasco with Kant-leak Kleets packed in the roll.

Write for samples and the Good Roof Guide Book.

Oak Flooring

Every **builder, owner** and **investor** should insist on OAK FLOORING. Its natural beauty combined with its **economical** and **durable qualities,** makes it the **King** of **Flooring.** Any truthful landlord or architect will tell you that OAK FLOORING **increases** the **renting** and **selling values** of any building more than any other kind of Flooring.

OAK FLOORING will harmonize with any kind of trim and is susceptible to any kind of finish. It is **rich** and **cheerful** in color, and imparts an air of refinement and elegance to a home.

OAK FLOORING ⅜" thickness by 1½" or 2" faces can be laid over old floors or over cheap sub-floors in new homes at a very low cost. It is cheaper than carpets or Pine Flooring.

OAK FLOORING is made in four grades in the 13/16" thickness and two grades in the ⅜" thickness. It is adaptable for the humblest of homes or a palace.

Write us for further information.

INVESTIGATE Compo-Board

Best for Walls and Ceilings.

Better then than and plaster. More economical and durable. Can be put on in any weather and will stay up and look well as long as the building lasts.

Compo-board is made of strips of thoroughly dried lumber well glued. These strips are then covered with a specially prepared moisture proof paper, which is cemented under intense heat and pressure.

This makes a wall lining that will last indefinitely. Cannot crack or crumble off. Cannot chip off or mar by banging furniture into it. It is moisture and cold proof and fire resisting. Warm in winter and cool in hot weather.

Beside being a wall lining, Compo-Board has many other uses around the house and in the yard, in the office and factory. For remodelling the house or finishing off an extra room in the attic or basement, it is ideal. Summer cottages can be made as warm as the city home. Use it for partitions or back plastering.

Compo-Board can be had in strips four feet wide and one to 18 feet long, in any length in even feet.

SEND FOR SAMPLE AND BOOKLET

Fully describes Como-Board and its many uses and advantages, and the sample will show you what it is.

TEN DAYS' FREE TRIAL

If you will take this ad to your hardware dealer and ask him to comply with this offer he will gladly do so; or, if he does not handle our squares and will not order one for you, write us, giving your banker's and grocer's names as reference. We will ship you one, express prepaid.

Guaranteed Accurate and to Remain So

The main feature of our new Take-Down Square is that it will always stay true. It is so constructed that the tongue is held down into beveled bearings by a spring, and these bearings are made so as to take up the constant wear which comes in taking square apart and putting it together, thereby producing constant accuracy. Rust-proof canvas case with each square.

	Polish	Ox. Copper	N. Plated on Copper

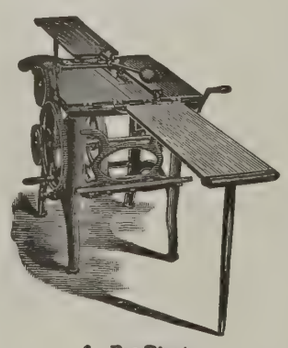
MASTER BRACE

The general appearance of this Brace rejoices the lover of fine tools. The metal parts are handsomely nickeled and the head and handle are of highly finished cocobolo. Both head and sweep-handle are ball-bearing, reducing all friction to a minimum.

All ratchet parts are covered and in that way protected from dust. The ratchet teeth cut directly upon the base of the tail socket, in a manner least likely to get out of order.

It is impossible for the chuck to work loose, whether the ratchet is worked left or right, because of the manner in which it is attached to the sweep by a flat-head machine screw and a patent washer, which is in the shape of a shallow cup.

It is in the chuck, the most vital part of any bit brace, that Millers Falls skill in brace-making has culminated. The sleeve is of a new pattern, just fitting the hand, and is reinforced at the lip to meet the strain at that point. The tail socket is made from solid bar steel, unbreakable under the severest usage. The jaws are so hinged upon a spring as to transmit any strain to the stout sleeve.



The jaws open parallel and close to conform to the shape of the bit used. Three grooves cut lengthwise in each jaw, making eight points of contact, insure the tenacity of grip.

The Master Brace is made in 4 sizes, with 8, 10, 12 and 14 inch sweep.

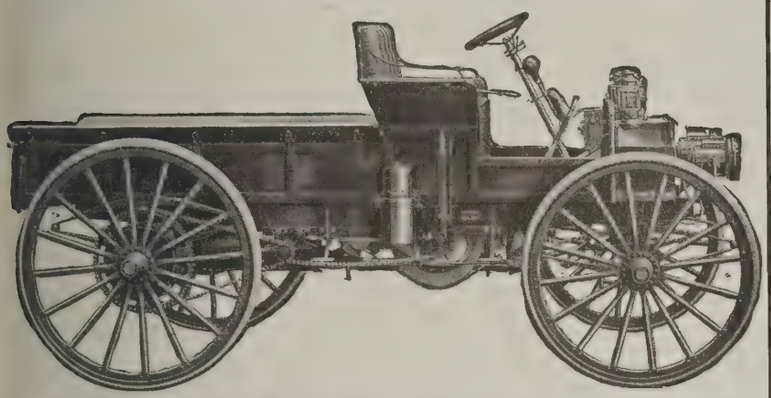
GREYHOUND HAND SAWS

SPEED & EASE — TRADE MARK.

The more you know about hand saws the more you can appreciate "GREYHOUND" hand-made hand saws, with their easy-running and rapid cutting qualities and wonderful durability. This saw will be imitated by others—but not equalled.



They are made from Bishop's Refined "GREYHOUND" Steel—a material which leads everything yet produced for use in hand saws. The purity of the steel, the toughness, the even and accurate temper, gives a saw that is the most suitable for particular work, and the most practical for ALL work where a hand saw is used. Made in both straight and skewback, also narrow patterns. Specify which you desire. Remember our warranty accompanies each saw. And the warranty means that if 30 days' trial does not convince you that the "GREYHOUND" saw is the **best** for your use, you get your money back.

Order one today and let us take all the risk. If you want literature first, write us.

Good Leads Make Clean Marks

A carpenter's pencil is a small thing, but the mechanic who puts a poor one in his kit is likely to be bothered by bad work and lost time.

Many an open joint in an otherwise good job is directly traceable to a gritty, brittle pointed pencil that wouldn't mark plainly enough to furnish a true saw guide.

E. C. S. Carpenter Pencils

will never serve a painstaking worker that way.

Of course, they mark plainer on a smooth board than on a rough one, but, smooth or rough, your tool will never lack a clear guide if the work is laid out with an E. C. S. Carpenter Pencil.

These pencils hold a very fine quality of lead of great toughness. The casing material is fine, straight-grained cedar. The parts are thoroughly glued together and *won't separate.* All in all, the E. C. S. Carpenter Pencil is the most *satisfactory* one made today for mechanical purposes.

THE WAGNER BUNGALOW, built in Chicago, Ill.

NATIONAL BUILDER DESIGN No. 345

L. E. Russell, Architect, Chicago, Ill.

For Floor Plans, Elevations and Details, See Supplement Sheet of this number. Estimated Cost, $4,725.89

Probably no cause has contributed more to bungalow construction than apartment house life. The convenience of having all the rooms on one floor has been carried to the suburbs and country, where such construction was considered not only impossible, but positively unhealthy to sleep so near the ground. In the cities the high value of land is perhaps sufficient reason to economize by piling one house on another, but in the suburbs this reason is not so apparent. The bungalow has been called a one-story flat, which perhaps it is, with the added charm of being set in a garden with plenty of light and air. It will be noticed that most of the bungalows are owned by city people who are accustomed to one-floor life and know its convenience.

In the Wagner Brick Bungalow we have an arrangement particularly adapted to a northern climate. A vestibule is needed to protect the house from the storms and cold of winter as well as the dust and heat of summer.

The relation between the various rooms is such that each is readily accessible from another, requiring much less work for the housewife.

ESTIMATE OF WAGNER BUNGALOW

Materials are figured at Omaha prices. Carpenter labor figured at 40 cents an hour.

EDITORIAL NOTES AND COMMENTS

That we want better, and more scientific workers in all our industries, goes without further argument.

* * *

Men and women properly trained, and made conversant with all the details of their various callings, make the best, the most useful and profitable citizens a country can possess, and form its greatest asset, besides being a nation's most formidable bulwark for the defence of her liberties, and the conservation of the welfare and happiness of the people.

* * *

Twelve or fifteen millions of dollars are expended by the government on the building and equipping a single Dreadnaught, whose life will not be more than ten or twelve years, while a hundred thousand valuable boys and girls whose services could have been rendered from ten to fifty percent more productive, during their present and future lives, had those millions been spent on them in giving them a thorough industrial, mchanical or agricultural training, at the proper period of their lives.

* * *

Battleships may be necessary—at times—trained mechanics, and expert agriculturists are necessary all the year round, and all the years in the cycle. An industrious community of expert workmen create more value than can ever grow out of a fleet of battleships, and the nation will be stronger and in a better position to ward off, and resist aggression, in any form, than if the country was encompassed by a line of steel fighting machines; and it is our opinion that if less money was spent in constructing these huge sea monsters, and a little more spent on building up and training the minds of the rising generation on lines leading to expertness and skill in manipulation and study of economy in the use of materials, in all sorts of structural work, the investment would produce overwhelming returns, and the cost of resource conservation, would be much less.

* * *

With some such object in view, Carroll S. Page, chairman of the committee on Cuban relations in the Senate, introduced a bill in the Senate on April last: "To co-operate with the States in encouraging instructions in agriculture, the trades and industries, and home economics in secondary schools, in maintaining instruction in these vocational subjects in state normal schools, in maintaining extension departments in state colleges of agriculture and mechanical arts, and to appropriate money and regulate its expenditure of one cent per capita per month by the National Government, which is the amount the bill calls for, if expended under the wise direction of properly organized authority, would do much to bring about results absolutely essential to the welfare of the great mass of boys—and girls also—of our land."

* * *

In a letter to the Editor of this journal, Mr. Page writes:

"The high schools, the academy and the college are taking excellent care of those boys who are financially able to avail themselves of their advantages, but it requires only superficial examination to show that the average boy, on arriving at the age when he must begin, because of lack of means, to be a bread-winner for the family, is neglected by the state and in far too many cases, following the lines of least resistance, drifts into a cheap manhood.

"That Germany is now outrunning us in the race for commercial supremacy is universally conceded. In my judgment, this is due in a large measure to the fact that when the German boy reaches the age of 12, 13, or 14, his characteristics, his physical equipment, the bent of his mind—his idiosyncracies, so to speak—are carefully ascertained and he is given the training which equips him for the life work which he decides to follow."

* * *

"Not so with the American youth of the great middle class, especially in our villages and cities. He is turned adrift, and the question presented to his mind is, not what will my future life work be? but rather, Where can I get a job that will furnish me the wherewith to buy my clothes and pay my entrance with my best girl to the moving picture show? If he can find a position as bootblack, newspaper vender, or messenger boy, he is content. In any event he follows the lines of least resistance and takes the work nearest at hand with little or no thought as to growing up into a well-rounded manhood. If he be a farm boy, he works along without specific training, and becomes another of that great number who secure from the soil only half the profits they should."

* * *

The adoption of this bill, or something similar to it, would certainly be of great benefit, not only to the young people of the country, but also to employers, business men, and every person who is compelled to earn a wage, employ or superintend labor of any kind. We have no adequate apprenticeship system for training skilled workmen, and our manual training schools—though doing excellent work as far as they go—are neither numerous or efficient enough to supply the demand for competent mechanics. In consequence of all this, the country is filled with incompetent men and advancement and progress are retarded and business enterprises handicapped, and the nation suffers to a much greater extent than dollars and cents can illustrate. Mr. Page's bill makes provision for state assistance in connection with the Federal grant, thus throwing a part of the cost of maintenance on the states, which seems to us the proper thing to do. It is to be hoped, our legislators in their combined wisdom, will see the way clear to make a law of this proposition.

* * *

Misery loves company, for which reason friends of the National Gallery of Great Britain are introducing Westminster Cathedral whenever derogatory remarks are made about the home of England's great painters or architects. Because of the little meaningless cupolas on the National Gallery, it is profanely known as the "cruet stand." The $1,500,000 Catholic Cathedral at Westminster, the construction of which was finished a year or so ago, is now known as "the factory."

It cannot be associated with the Singer building or the Metropolitan because its tower, while the most lofty in London, is a dwarf compared with either of the New York towers. Considered architecturally it is held by some to be a monstrosity. Its merits are not added to by the fantastic brickwork.

To support its 165 foot roof, the builders had to put in such massive oblong pillars that not nearly one-half of the congregation when the church is filled, can see the altar. The other day the Catholic officials from over seas attended a state ceremony in the great place. The result was a huge attendance. Only those in the middle aisle could see. Those in the great side aisles and in the balconies were barred by the pillars. Such is the result of strained art.

WANTED, A RUST PROOF METAL

MANY carpenters' tools that were formerly made almost exclusively of wood are now made of metal. Take plane stocks, for example, and in the old days these were made of wood in a great variety of sizes all the way from short smoothers up to the mammoth jointers 30 and 40 inches long and often each workman made his own planes and trued them up occasionally. Today many of these plane bodies are made of metal which insures their remaining true on the face and not warping, and also there has been attached to them many conveniences for adjusting the bits and they are a decided improvement on the old time plan.

The same thing is true with a number of other tools. There is more metal and less wood in tools, which contributes to stability and durability and yet there is one general complaint, and that is these metal tools and tool bodies rust easily. If one is left on a damp piece of board or is caught out in the rain or has been handled by perspiring hands and is laid up for a day or two it is discolored and rusted. Or, if out on a job and there comes a shower of rain and blows into the tool shed there is sure to follow a lot of rusty tools and a big job of cleaning and drying and polishing over with oil. What we need and what some inventor ought to get busy on is a metal for tools and tool bodies that is rust-proof. We cover wood with paint to prevent the weather affecting it and some parts of metal can be covered with a paint or enamel to protect it in the same way, but the parts being used cannot be so covered because the covering material would wear off. So, what we need to solve this problem is a metal or composition that will resist the moisture of the elements, which cause rusting of ordinary tools. Maybe we already have such metals if we would but work them into tools and maybe it would be necessary to get something entirely new. Anyway, what is wanted to put the modern tools in still a higher class is a rust-proof metal in the make-up that will retain its shape and resist the moisture and other elements tools are ordinarily exposed to.

CALIFORNIA'S MODERN MISSION BUILDINGS

By HORACE F. STOLL (Continued from August.)

STATUE OF FATHER JUNIPERA SERRA, FOUNDER OF THE MISSIONS, GOLDEN GATE PARK, SAN FRANCISCO.

There is scarcely a city of importance on the Pacific coast that does not boast of a mission schoolhouse. In fact, California has advanced as rapidly as any state in the Union in the development of the modern public school building. It was but a few years ago when the badly arranged and poorly lighted and heated school building was the rule, now it is the exception. The large rooms, spacious passage ways, open promenades, and low buildings insure safety for the pupils and teachers.

At San Jose, the center of the beautiful Santa Clara Valley, in Central California, I had an opportunity to inspect the San Jose Mission High School, which is the first California high school building constructed on the university plan. It consists of five separate and distinct buildings so grouped and connected as to form one general whole. The administration building, with its massive towers, is the central feature, on either side are the classical and science buildings and at the rear are the domestic science and manual arts building. They are all of the same type of mission architecture with rough cement plaster exteriors and red tile roofs and are connected by three cloisters. The entrance to the patio is through a mission wall, the reinforced concrete posts of which are replicas of the large towers in the main structure.

In a few weeks the Mission State Normal School, which is also an ornament to San Jose, will be ready for occupancy. It enjoys the distinction of being the largest reinforced concrete school building, in ground area, in the world. It covers a site 246 by 472 feet and with the exception of the tower in the center, is two stories high.

CARNEGIE LIBRARY, ST. HELENA, CALIFORNIA.

The school is built in the shape of a rectangle, broken up slightly by pavilions and buttresses and is absolutely monolithic. The concrete was poured by gravity from three high towers, 43,840 sacks of cement being used in a mixture of one to six (three parts river gravel and three parts crushed stone. It might be interesting to add that the reinforcement used amounted to something over 200 tons besides 116,000 feet of wire fabric. More than 1,300,000 feet of lumber were needed. This includes the cribbing, forms and interior finish. Forms were required for about 265,000 square feet of concrete. The exterior of the rough walls are covered with a pebble dash of white Portland cement. The interior of the corridors is treated stipple finish, while the interior of the building has the hard wall sand finish.

There are thirty-eight large classrooms, the average size being 24 by 32 feet. Open arcades on the center quadrangle afford comfortable passage from one classroom to another. The library is the largest room in the building and is a gem in itself. It is two stories high, 60 by 97 feet, and void of columns which obstruct valuable space and light. The ceiling is done in ornamental plaster, with panels of Corinthian pilasters in staff and stucco. There are accommodations for 40,000 volumes, the equipment including 22 double steel stacks, each one 14 feet long. There is also room for 44 reading tables.

I give these details to show the innovations introduced in California's new educational institutions. The San Jose Normal School, by the way, was erected at a total cost to the state of $272,000, or a little less than 16½ cents per cubic foot. It is one of the best bargains California has ever made.

At the Leland Stanford, Jr., University, at Palo Alto, the old mission architecture has been reproduced on an imposing scale. Gathered about a court 528 feet by 246 feet, enclosing an area of

SANTA FE STATION, OAKLAND, CALIFORNIA.

three and one-quarter acres, are the twelve buildings of the inner quadrangle. They are connected by a continuous one-story open arcade, facing the court, that reminds one of several of the missions in Southern California. The soft buff sandstone, the great expanse of red tile seen through the wide arcades, the simple but graceful arches, the wealth of tropical foliage, distant glimpses of trees and foothills and mountains—all give one an impression of peace and academic seclusion and make one feel that the adoption of the mission architecture at Stanford University was a happy inspiration.

And writing about colleges reminds one of the novel mission campanila at Mills College, California's foremost girls' seminary. It was presented some years ago by Mr. and Mrs. F. H. Smith, and cost in the neighborhood of $10,000. The clock tower and belfry combined, built of reinforced concrete, stands in the midst of venerable oaks, towering eucalyptii and flowering shrubbery. The ten bells were chimed at the World's Fair in Chicago and were brought to the Midwinter Fair in San Francisco, after which they were purchased by Mr. David Hewes and presented to the college.

Over at Idora Park, Oakland's great children's playground, is a characteristic mission wall or parapet that has attracted much attention. It is constructed partly of solid concrete and partly of

wood, metal lath and plaster. At the corners are miniature towers and at set intervals between, alternate openings filled with artistic ironwork and big piers mounted with wooden crossbeams covered with rambling vines that also festoon the wall.

Until the great conflagration of April, 1906, San Francisco fought shy of the mission type of architecture. It is possible that if their Mission Dolores were as imposing structurally as some of the missions in the South, California's metropolis might have been sooner inspired to imitate its principal features. I was surprised to find the mission's walls snowy white. This was due to a liberal coat of whitewash recently administered, but I was assured that the elements, in a few months, will undo the good work of the fathers, who have endeavored to make the mission as comfortable and attractive as possible, pending the construction of another imposing edifice on the corner.

The cathedral, which overshadowed the modest mission founded by the padres in 1776, was so badly shaken by the earthquake that it had to be torn down. Its removal has added tremendously to the dignity and impressiveness of the staunch little church whose

ST. MARK'S PROTESTANT EPISCOPAL CHURCH, BERKELEY, CALIFORNIA.

cross rises white against the blue sky. The mission did not entirely escape injury. Cracks were made in the walls and those left from previous earthquakes were widened. Several of the roof trusses, tied together with rawhide, were torn apart. The tiles were all displaced and many of them thrown to the ground and broken. In the interior, pilasters were thrown down and portions of the wall fell in. But the interior has been practically restored and before long the unsightly shingles on the roof and the wooden walls that protect the abode from the elements in the rear will be replaced with tiles and concrete.

A few blocks from the mission is a very striking little one-story mission block, with a miniature tower at the corner. The rough gray walls, bright white woodwork and warm red tiles made such a pretty color combination that I stopped to examine it more closely. Finding the corner division was given up to a saloon, fitted in mission style, I could not help picturing the look of righteous indignation that would have distorted the face of some pious old mission architect if, in his ramblings, he had stumbled on this enticing resort. It seemed almost sacrilegious to have a saloon in such a prim, sanctimonious looking building, and yet I came to the conclusion that since there must be places where one can quench his thirst, they might as well be artistic.

ROOFING BY THE STEEL SQUARE—No. 4

THE HIPPED ROOF

WHAT may be called roofing proper is the next stage of the work, the style of the roof shown in the article being hipped at each corner. This requires, in addition to the common rafters already dealt with, the "hips" or diagonals, and the shorter "jack" rafters, "strutters," or "cripples," which fit to the hips. What a hipped roof really is can be seen from the two photographs, Figs. 18 and 19; the one showing the elevation from

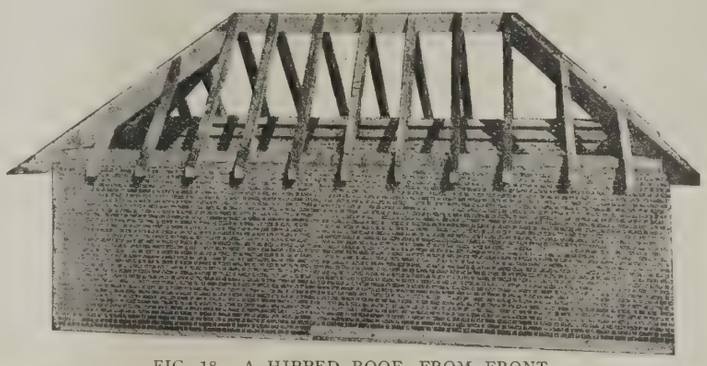

FIG. 18. A HIPPED ROOF, FROM FRONT.

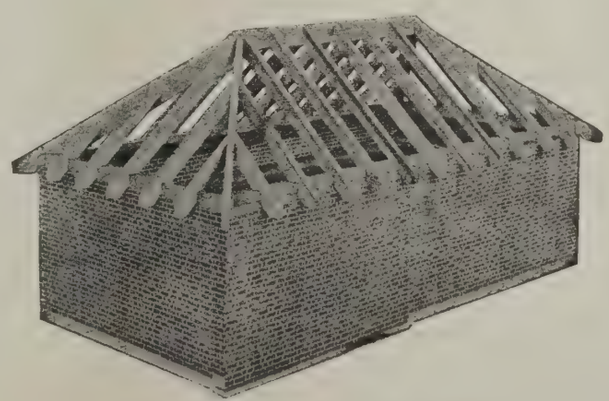
the front, and the other the elevation from a corner point of view. Fig. 20 shows the actual working elevation, and Fig. 21 the plan of the complete roof.

An ordinary hipped roof is always shortened at each end equal to half the width of the building, less half the thickness of the ridge, so that the rafter which rests against the end of the ridge, at the top, and which is sometimes (and in the writer's opinion rightly so) called the "jack" rafter, comes the same length as the ordinary rafters. This rule may be departed from in some cases, but it is only to suit special conditions, which may at the present time be left out of calculation.

As an object lesson, consider the present roof to be 21 feet wide and to be of square pitch. The rafters will thus have 10½ feet rise, and the correct length for these will be found by going upwards in steps as shown in Fig. 22, with each part of the square at the 10½-inch mark, level with the back of the rafter. Twelve of these steps, as shown, will then take us up to the required height, and the hypotenuse of the twelve triangles will give the length of the rafter from the backing to the point of the top. The backing is the point at *A* (Fig. 23); any length below this must be added as required. The successive positions of the square in measuring up the rafter are shown in Fig. 24, and, of course, to assist in getting these accurate, the gauge shown in a previous article may be used.

To obtain the length of the hip required, make a drawing as Fig. 25, on which the outside line of the plates is *B*, the ridge line



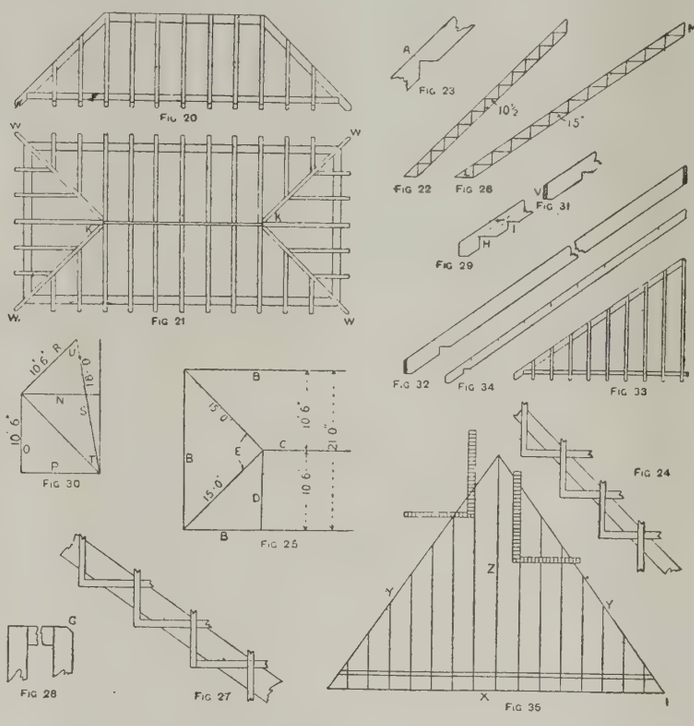


FIG. 19. A HIPPED ROOF, FROM CORNER.

C, the outside common rafter *D*, and the line of the hips *E*, all in plan, but correct to scale. On measuring along the line *E*, it will be found that this is 15 feet; thus is obtained the length of the hips in the same way as was that of the rafters, only instead of holding the square to the 10½-inch mark on both parts, the one must be to the 15-inch mark, as in Fig. 26, and as shown larger in Fig. 27.

This is correct in theory, but not in practice, as scantlings are

being dealt with instead of lines, and we must make allowance for the thickness of the timber. First as to the bottom end of the hip, the length given, or rather obtained above, is from the extreme corner, as Fig. 28, but as the corner must be cut off to obtain a seating for the hip, as at *G*, an allowance of an inch must be made for this. Owing to the hip when fixed having to stand diagonally with the other rafters, the backing will need to be practically half as deep again. The inch left on at *H* (Fig. 29) will increase the backing as nearly correct as it can be got in this small scale, making it as at *I*. At the top end of the hip these lines really go to the center of the ridge, but as the hips have to be fitted to each side of a rafter, as *K* (Fig. 21), the length must be reduced by an inch here, which will make it correct.

The horizontal and vertical numbers of the square as held in finding the length of the hip will also give the correct angles, respectively, thus *L* (Fig. 26) will fit on top of the plate, and *M* will fit to the rafters at the top.

Another way of obtaining length and bevels is given in Fig. 30, where the lines *N*, *O* and *P* represent the side and end plates, and ridge, respectively, the diagonal being the line of hip. At right angles to the latter line *R* is made, and at the distance equal to the rise of the roof, another diagonal *S* is drawn, which will give the length of the hip from backing to ridge, and the angle at *T* will rest on the plate, *U* fitting the rafters at the top, or in other words, *T* is the angle for the horizontal, and *U* for the vertical cuts.

The top end of the hip rafter will have to be cut to a point, to fit into the angle, and the two sides of this point must form a right angle one with the other when cut. It does not follow, however, that two cuts at an angle of 45 degrees are correct, as this is only so in a horizontal plane, the angles from the back of the hip varying with the pitch of the roof, and the method of getting these correctly will be given later on.

So far the hip from the backing upwards has been dealt with, but the diagonal position of the hip also affects the length of the foot, in the case of a square pitch the same as the one under consideration at present, the difference being in the proportion of two to one. That is, if the foot of the common rafter runs down 6 inches from the backing to the extreme point, the hip will run down 9 inches, and the vertical cut at the foot (*V*, Fig. 31) must be made to the same angles as the top, so as to line with the rafters on each side of the roof, as at *W* (Fig. 21).

In setting out for the jack rafters (or strutters) these may either be made even along the plates, as shown in Fig. 21, or they may be made to come evenly at the feet, as Fig. 33, or the medium may be struck, and the shortest allowed to come slightly further away from the hip. From the utility point of view it is immaterial, but for appearance the even spacing of the feet is the best, and to set these out, the distance from the middle rafter to the hip at the extreme point must be taken and divided up so that the number of spaces is known. The hip can then be divided up into the same number of spaces as in Fig. 34. Then on making a drawing to scale of the hip part of the roof, as Fig. 35, the length that each short rafter must be less than the common rafters will be found by applying the square as on the left of the drawing, and the angle of the top cut by applying the square as on the right, the hypothenuse giving the correct cut, which, as shown, cuts the two parts of the square at 23 inches and 16 inches, respectively. The down cuts, as well as the feet of these rafters, will be the same as on the common rafters.

The lines in Fig. 35 show the centers of the rafters when making the drawing to obtain the angles from. They should be on a comparatively large scale, and two lines giving the thickness of the rafters should be made. It is most convenient to work from the longest side, that is, the side towards the central rafter.

In Fig. 35, the line *X* shows the feet of the rafters, *Y* the length of the hip and *Z* the length of the common rafters.

SUDDEN RISE IN POPULARITY OF CYPRESS

INTERESTING FACTS ABOUT "THE WOOD ETERNAL".

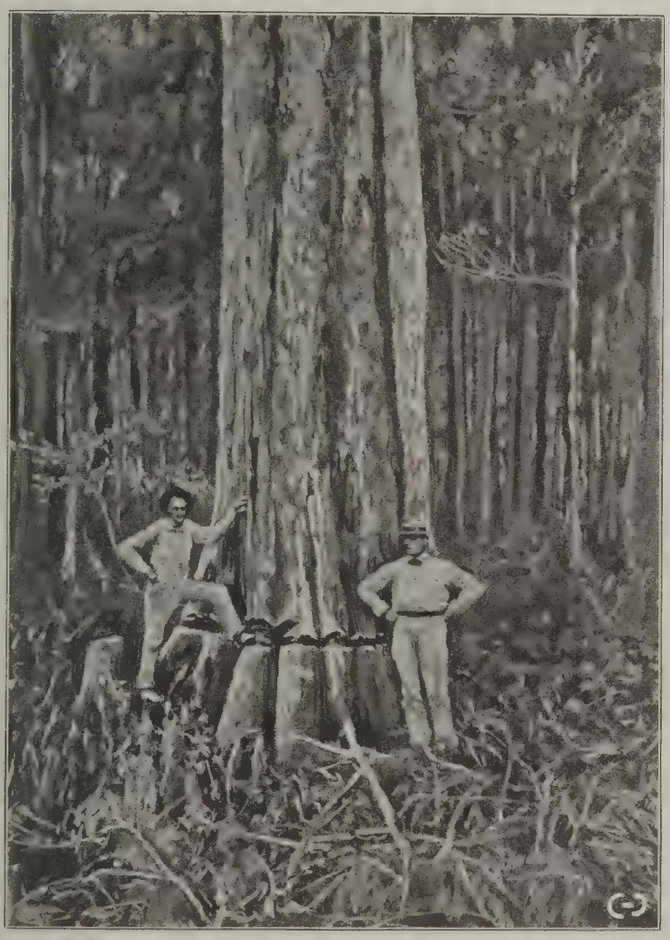
Historians claim the early abodes of man were in the rock caves in the hills. It may be. Certain it is that architecturally stone and brick have left many interesting ruins, long since unfit for habitation. At the present time the great majority of people are living in frame houses, and even in the remainder wood plays a very important part as floors, trim, furniture, etc.

Among the qualities found in wood which render it particularly adaptable for its use as above, are first, its general distribution, being found practically wherever man can live; second, the ease with which it can be fashioned to suit our needs; third, its strength and stiffness, compared to weight, making a lasting product. Other qualities more or less modify the above and only emphasize its use by civilized man.

In many positions and for many uses the permanence of wood is of small consideration, as even the softest woods last a long time and stand considerable wear and tear before giving out. Frame buildings several hundred years old are standing today, the wood being practically as good as new. There are also buildings only a few years old which already show signs of decay. Proper protection from the weather and dampness, with proper ventilation, will add years to the life of any wood, while there are other woods which seem to be proof against decay and the attacks of insects, worms and other parasites.

Where each country and state has been so favored with timber growth, it is but natural that each should use the material nearest to hand. It is possible to find black walnut, now almost priceless on account of its scarcity, used for framing in the older houses in Indiana and Illinois. Oak, too, has been used for sills, girders, etc., on account of its local prevalence. White pine has been universally used through the northern states until the extent of the cutover land has given the general public the erroneous idea that practically little remains available. Fortunately there are yet untouched such immense forests of this fine wood that a century to come can be supplied at the present rate of consumption.

It is a curious fact that not in all cases is the most desirable or appropriate wood used. In many instances it is a case of using the kind and quality nearest the job, or which could be obtained at the lowest price. The average consumer does not specify the kind of wood with anywhere near the same discrimination he applies to other things. This, of course, is mainly due to popular ignorance of the distinctive qualities of different species.



But it is not always enough that wood be convenient or merely of ample strength and durability. For the finer finish a beautiful grain must be present, or color, or perhaps an enameled surface is desired, as for a colonial interior or a bathroom. Here a wood must be selected without so much regard for mere cost or proximity. It must meet these higher conditions.

One of the woods which meets all-around requirements to a

remarkable extent is cypress. In the United States there are some seven recognized varieties, of which only one, "bald cypress," is of great commercial importance. This wood varies somewhat in different localities, being known as red, white, yellow and black cypress. Its growth is very slow, but the trees attain considerable size, sometimes a diameter of ten feet, with a height of one hundred and fifty feet, although the usual run is from three to six feet in diameter. The older trees are estimated to be at least 2,500 years old, so that the replacement by new growth is a slow process and does not keep up with the cut. The average cypress tree of commercial size will show an age of 500 years.

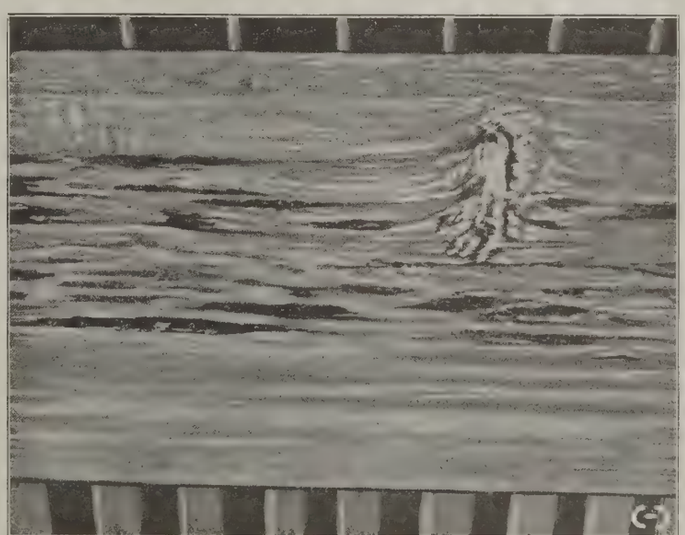
Of the peculiar decay-defying character of cypress the United States Forest Service (Bulletin 95), says: "Many instances of use exceeding a century are cited to show its lasting qualities. This is not only true when used as roofs, but for other purposes." The same document refers to several cypress roofs in New England on record as having given actual service for 250, 228 and other long terms of years, "one at Clifton, Staten Island, had 200 years to its credit when last reported, and was still in use."

"Cypress is put to almost every use as an interior trim for houses. It may be finished in natural color or stained. The wood contains little resin, and thus affords a good surface for paint, which it holds well. It is much used for door frames, window frames, transoms, ceilings, wainscoting, panels, doors, sash, balusters, inside blinds, brackets, newel posts, grilles, mantels and to some extent for flooring. It is a popular wood for kitchens, where it is subjected to dampness and heat. It shrinks, swells, or warps but little, and is used for drainboards, sinks, kitchen and pantry tables, cupboards and kitchen cabinets. For the same reason it is used for breadboards and wooden implements about the pantry, ironing boards, and clothes driers."

CYPRESS TREES ARE 75 TO 140 FEET HIGH, 3 TO 6 FEET IN DIAMETER AND AVERAGE 500 YEARS OLD WHEN CUT FOR LUMBER.

"For the parts of houses exposed to the weather it serves equally well. As siding it practically wears out before it decays. When made into porch and portico columns it retains its shape, holds paint, and has sufficient strength to sustain necessary loads. It is placed as cornice, gutters, outside blinds, pilasters, and railing and is much used for porch floors and steps."

The growth of cypress is largely confined to swamp and low lands of the states of the South from Maryland to Texas. Possibly no class of lumber is harder to get at, cut and get to the mill. Where railroads are not possible, it is customary to dredge elaborate canals through the swamps, to which the logs are drawn by engines and cables, and through which they are floated to the mills. The illustration will give an idea of the labor of constructing such a channel, it being frequently necessary to remove sunken logs with dynamite. Many of the canals are forty feet wide and ten feet deep, with fleets of tugs or "tow-boats."



Cypress is practically immune to the ordinary diseases and insects which attack timber, but it has one which is seldom found in other woods. Some trees show that they have been attacked by a sort of fungus which fills the wood with small holes or spots, the appearance being that shown in the illustration. Wood so affected is called "pecky cypress" and it is claimed that in spite of its looks wood so affected will outlast even the famous heart cypress which is known as "the wood eternal." Logs buried many feet in the swamp show the marks of having had this disease and are in good condition, although their age is estimated at 30,000 years.

CANALS ARE BUILT AT ENORMOUS EXPENSE THROUGH THE SWAMPS. THEY MUST BE LARGE ENOUGH TO ACCOMMODATE TUGS AND BARGES.

"Pecky" cypress, the "vaccinated wood," while of course not so strong as perfect cypress, is used by railroads for ties, posts, foundation timbers, fencing, etc., and shows remarkable durability.

The interesting fact about "pecky" cypress is that the fungus which attacked it untold years ago evidently failed to make headway as on other species of trees and died soon after starting, being defeated by the presence of a peculiar oily quality—which scientists have named cypressene. It has no parallel and to it is thought must be due the historic long life of cypress wood under even the worst of rot-influences.

PECKY CYPRESS IS NOT AS HANDSOME A WOOD AS THE HEART CYPRESS, BUT IT IS VERY DURABLE.

PERFORMANCE OF BUILDING CONTRACTS By W. J. STANTON

(Continued from August.)

WHERE a building contract requires the use of hard bricks in the construction of the walls of a building, the use of a considerable quantity of soft bricks is not a substantial compliance with the contract. So, also, where the contract required the use of Yankton cement which cost $3.40 per barrel, while Milwaukee and Louisville cement at a considerable less cost was used, and two hundred barrels were required, the foundation wall did not taper up six feet from a three-foot width at the bottom to sixteen inches at the top but was blocked into a sixteen-inch wall two feet from the bottom at a saving of six thousand bricks to the contractors, the plate glass was not free from sand holes, and the rear and party walls were not built of selected brick as to color—the contract was held not to have been substantially performed. Where the contract requires the contractor to make a "water-tight" cellar by pursuing a certain method, the making of a "water-drained" cellar is not a substantial performance. Likewise where a contract required a foundation to be laid according to the usual building regulations and a cesspool to be constructed in a certain manner and cemented throughout, but the contractor failed to do so and failed to make the cesspool water-tight, in consequence of which the owner was required by the city officers to make it water-tight, is not a substantial performance of the contract.

Where the contract required the installation of screens and hardware made of bronze wire and doors fitted with Laramie checks, it is not a substantial compliance to use "bronzed" steel wire, which is worth only one-fifth as much as bronze wire, and merely bronzed hardware and no Laramie checks. Where the contract for the construction of a creamery required the building to have a one-third pitch to the roof, but it had a pitch of four inches less, which was, however, capable of shedding the rain; a large part of the shingles used were of inferior grade and so laid as to leave holes in the roof; and the siding used was unsound and split—the defects were held to be such as not to amount to a substantial performance, even though they could be remedied for one-fifth of the entire cost of the creamery when fully equipped.

The failure of a contractor to put three coats of plaster on a clothes closet wall according to the terms of his contract, will not, as a matter of law, defeat recovery by the contractor. Where the contract requires the buildings to be plastered and a certain chimney flue to be constructed, the failure to plaster a large room in the basement and to build the flue which was to be constructed constitutes a failure to substantially perform the contract. Where the contract for the decoration of a store room required the contractor to cover wood partitions with canvas to make a suitable surface to work on, and that the materials used should be first-class and the work done in a workmanlike manner, the fact that no suitable surface was made on the wood partition will not preclude a recovery on the basis of a substantial performance, where the contract was otherwise properly performed.

Where under a contract to repair an old house and build an addition to it no part of the second coat of paint upon the new part had been put on, two doors were not hung, no lock or fastenings on the front door and windows, and the workbench of the carpenters and paint which was to be used were still in the house, it was held that there was no such substantial performance as would allow a recovery after the destruction of the house by fire. Under a contract for the painting, varnishing and graining of certain buildings, the fact that some small places in the buildings were not properly grained and finished, the cost of which would not exceed five dollars, was held not to prevent the contractor from claiming a substantial performance.

The fact that some brick work was unfinished and the debris was not removed from some of the floors, the total cost of doing which would not exceed three dollars, will not prevent a recovery. A contract to perform the mason work on a building is substantially performed even though the cellar has not been cleaned and the rubbish removed. A contract to construct a barn cannot be said, as a matter of law not to have been substantially performed because the large doors have not been hung. A contract to furnish the galvanized work and tin roofing of a freight shed, together with two gangway openings, is substantially performed where the two openings were omitted through a mistake and the cost of making them did not exceed $35. Where a contractor intentionally failed to trowel-strike the brick walls of a building, used brickbats in the inner and outer tiers of walls, left holes in the walls by mortar falling out and the improper setting of the bricks, and used an inferior quality of brick in the structure, the defects are of such a serious nature that the contract is not substantially performed.

The rule of substantial performance does not apply where the variations from the terms of the contract are so substantial that an allowance out of the contract price for damages would not give the owner substantially what he contracted for. In many cases in determining whether or not the contract has been substantially performed, a controlling importance has been given to the cost of remedying the omissions, defects and deviations as compared to the contract price of the whole work in preference to a consideration of the character of them. Thus, where the contract price was $3,400 and the cost of completing the contract was $267, it was held there was no substantial performance. Where the contract price was $3,000 there was no substantial compliance where it would cost $350 to complete the building according to contract.

Where the contract price was $2,100 but the omissions on the part of the contractor amounted to ten per cent of the contract price it was held insufficient to show a substantial performance. A failure to finish work to the extent of one-seventh of the contract price has been held not to be a substantial performance.

It has been held a substantial performance where the contract price was $21,700 and the omissions were furnished at a cost of $154. A similar conclusion was held where the contract price was $17,393 and the omissions could be remedied for $317. So, also, where the contract price of a building was $48,700 and the value of the unfinished work was $2,274 the contract was held to be substantially performed. A contract calling for $800 has been held substantially performed where the cost of remedying the defects did not cost to exceed $75. The same conclusion was reached where the contract price was $390 and the omissions and defects did not amount to more than $14.

Where a building was to be completed by a specified day or render the contractor liable to certain penalties, it was held substantially completed where all that remained to be performed was the removal of the external rubbish, the remedying of a slight defect in the cellar, and a few other minor defects caused by the weather conditions.

The Supreme Court of Massachusetts hold that under the statute stating the allegation required in a mechanic's lien statement, it is not necessary, in a statement for a lien based on a contract to perform labor without materials, for a specified price, that the number of days consumed in performing the work should be stated.

A lumber company sold material for the erection of improvements upon real estate, furnishing items from time to time as desired until August 17th. On January 31st it tried to collect its bill, and failing to do so took security for its payment. The next day it sold two cans of paint and a brush to its debtor, and added its price to the bill, and sought to maintain thereon a material man's lien. Under these facts the Supreme Court of Kansas held that parties could not by such subterfuge increase the time for filing a statement of lien beyond the four months prescribed by statute.

The owner of land contracted for the construction of a building for $4,600, payable one-third when the concrete walls were finished to the roof and the door and window frames set in the wall, one-third when the roof was completed and the framework for the inside partitions and the joists and flooring installed, and the balance within 20 days after the house was finished and accepted. Thereafter the contractor for a discount of $200 in the price obtained a modification of the contract which was not filed, by which payments were made weekly as the work progressed, covered by bills for labor and materials and subcontracts. The Court of Errors and Appeals of New Jersey held that such subsequent agreement constituted a material modification of the contract, and that having been filed with the county clerk in pursuance to statute, a materialman, having furnished a greater part of materials after the contract was modified, was entitled to a lien therefor.

The Court of Appeals of Maryland holds that a city employing a contractor to perform a lawful work under its supervision or employing an independent contractor is liable for the negligence of the contractor in the performance of his work, and that a city making excavations in its streets must exercise due care to protect water and gas pipes, telephone and telegraph conduits and other agencies in the streets, and in protecting the life and property of abutting residents.

LEAVES FROM A STUDENT'S NOTEBOOK—No. 4

By GEO. METSON

NOTES ON COLUMNS AND STANCHIONS

OF cast iron columns, those circular in shape are the most common in use and the most economical in metal, and they also have the great advantage of having no angles to weaken them. The section shown in Figs. 2 and 3 are also commonly in use. In these it will be noticed that the angles are rounded. This is important as regards the internal angles, as in cooling, the crystals set at right angles to the enclosing lines of section, so that square angles would be a great source of weakness. Another point in designing in cast iron is that any increase in thickness of the metal must be made gradually. In order to test the trueness of the thickness of metal of a column as in Fig. 1, holes must be drilled. Differences in thickness of metal in columns of the shapes as Figs. 2 and 3 are noticeable to the eye, and can be measured with calipers.

Mouldings form a weakness, and are best added as separate castings as in Fig. 4, but small neckings are not so objectionable. Cast iron columns are now practically only used on account of the architectural treatment to which they lend themselves, small steel stanchions having to a very large extent supplanted them.

In order to spread the load over a larger foundation area separate base plates are used; these are shown in Fig. 5. Fig. 6 shows a method of carrying the ends of joists on cast iron columns.

FIG. 5

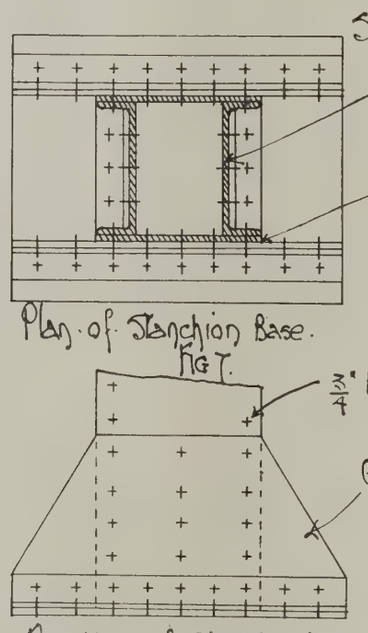

FIG. 8.

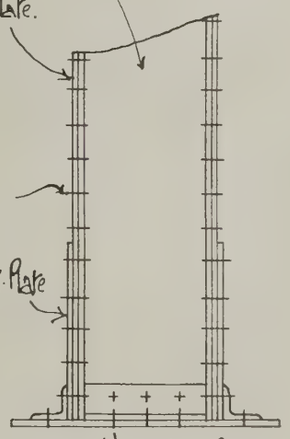

FIG. 9.

NOTE

¾" Rivets used throughout: those next stone to be countersunk.

Here can be seen the weakness of cast iron for columns as the flaw (if any) in the metal may be in the lug, and it is impossible to detect it, but cast iron has this advantage over steel for stanchions, although it be best to protect both from fire, yet it is not so important with the former as with the latter, as though under great heat it might crack, yet it would probably continue to support its load, whereas the steel stanchion would buckle, bend or entirely fail under such great heat.

Figs. 7 to 9 show details of steel stanchions, some of which call for special explanation.

Proceeding to design, let it be required to design a cast iron column to be 12 feet high, having to support a dead load of 42 tons. The following notes must first be given.

A column should never exceed in height thirty times its diameter. The diameter should be from 1-10 to 1-25 of the height. The thickness of the metal should be about 1-12 of the diameter.

The factor of safety (f. s.), used should vary with the length of the columns, taking 4½ as a f. s. for a column of height of 10 diameter and adding ½ for every additional 10 diameters, or part of 10 diameters; thus for a column of 20 diameters high use a f. s. of 5; for one of 30 diameters high use a f. s. of 5½. The columns to be perfectly fixed at the ends. Columns with large caps and bases are taken as having securely fixed ends.

The formula most commonly in use for columns, stanchions and pillars is Gordon's, which gives the approximate load in tons per square inch. It must be understood the solution only gives an approximate result. For truer results it is necessary to take into account the radii of gyrations, but this will be explained and examples worked out in a later paper.

Having found the breaking weight by the formula, a factor of safety (f. s.) must be used to ascertain the safe load.

Returning to the example to be worked, then our assumed diameter is 8 inches and the thickness of metal should therefore be 2/3 inches then

$$\frac{F\,A}{1+C\left(\frac{1}{d}\right)^2}=\frac{36\times(7\frac{1}{3}\times 3\frac{1}{7}\times \frac{2}{3})}{1+\frac{1}{800}\left(\frac{144}{8}\right)^2}=\frac{\frac{3872}{7}}{\frac{281}{200}}=394 \text{ tons nearly}$$

and using a factor of safety of 5 the safe load = 395-5 — 78 4-5 tons, which is on the right side of the 72 required and sufficiently near enough for all practical purposes.

The student must not be disappointed if his first attempt of assumed diameter and thickness of metal is out altogether as there is no certain way of obtaining the correct size—it must be done by means of "trial and error." Experience will of course aid him in assuming the diameter, etc.

Let it now be assumed it is required to design a steel stanchion of the same height to carry the same load, then, assuming H section

$$\frac{F\,A}{1+C\left(\frac{1}{d}\right)^2}=\frac{24}{1+\frac{1}{2000}\left(\frac{144}{8}\right)^2}=\frac{12000}{581}=21 \text{ tons nearly}$$

and using a factor of safety of 5 = a safe load of 21-5 or 4 1-5 tons per square inch, so that in one case $\frac{72}{4\,1\text{-}5}$ or 17.14 square inches of section will be required and a 9 inches x 7 inches x 58 lbs. will meet the requirements, its sectional area being 17.06 square inches.

The architect or the draughtsman would have turned up to Steel Merchants book of sections and tables and not have calculated, but the student should know how to arrive at the area of metal required.

It is always best to use stock sections. In built up stanchions, the space the stanchion has to occupy and the fancy of the designer will affect the design.

The same formula will answer for wooden pillars, the value of "C" being taken as $\frac{1}{250}$ and that of F as 2½ tons for good fir or deal and 3 for oak, but with wooden pillars the factor of safety employed should be 10.

Gordon's formula:

$$\text{Ultimate load in tons} = \frac{F\,A}{1+C\left(\frac{1}{d}\right)^2} : \text{ where}$$

F = ultimate resistance of metal, tons per square inch.
A = sectional area of metals.
C = a constant found by experiment, depending on the material and section used.
l = length of column in inches.
d = diameter or least width in inches.

Material.	Section of Column or Stanchion.	F	C
Cast iron	Solid round	36	$\frac{1}{400}$
Cast iron	Hollow round	36	$\frac{1}{800}$
Steel	Solid round	24	$\frac{1}{2250}$
Steel	Hollow round	24	$\frac{1}{3500}$
Steel	Solid Rectangular	24	$\frac{1}{3000}$
Steel	Hollow Rectangular	24	$\frac{1}{5000}$
Steel	L, T and +	24	$\frac{1}{5000}$
Steel	I and H	24	$\frac{1}{2000}$
Steel	Box or Compound	24	$\frac{1}{2250}$

THE ROCHESTER COLONIAL HOUSE

By WM. J. DUNN

For this home, lines of the old New England Colonial house are closely followed, and it is best adapted for a large or corner lot. Its construction is neither expensive nor showy, but hospitality speaks from every corner.

The foundation is built of cement blocks with tapestry brick facings above grade. The superstructure is of wood, while the exterior frame work is covered with matched sheathing, building paper and shingles laid seven inches to the weather. The shingles are stained a silver gray color while the trimmings are painted pure white. Blinds may be added and should be painted an apple green to get the best effect with present color scheme.

The entrance is on the side and for it the architect used for his prototype the old "Salem Stoop." Its charm lies in the beautiful design of the door and facings, while the trellis built at either side of the entrance with openings for two small windows, carries out the Colonial effect so eagerly sought.

The arrangement of the porch columns and the lattice work, while unique in design, is purely Colonial and forms an important decorative feature. The porch is private and can only be reached by two large French windows opening from living room. This is an ideal feature in a way. Both stoop and porch have red Welsh tile floors. Entering the reception hall, one is immediately impressed with the beauty of the staircase, with its broad landings of plain but simple design. The stair risers and spindles under the handrail are white enameled—a pleasing contrast to the other woodwork of red brick stained mahogany. The walls of the hall are covered with a tapestry wall paper of foliage design in brown and green. Here, as throughout the house, the curtains and draperies are chosen for Colonial effect.

To the right of the hall is the living room, extending the entire width of the house. It has a two-tone, green striped paper and is trimmed with mahoganized birch rubbed to an egg shell gloss. The fireplace has red brick facings and red Welsh tile hearth, both the brick and tile being laid with wide joints in white mortar. The mantel is also of mahoganized birch, designed in a simple manner. A built-in bookcase is at one side of the fireplace and at the other is a window seat with a low radiator concealed underneath French windows, open from the living room to the porch.

Simplicity is the keynote of the dining room with its hazelwood trim. Beneath a plate rack, six feet from the floor, the walls are covered with a red oatmeal paper while above gray oatmeal paper with figured cutouts is used. An artistic effect is also pro-

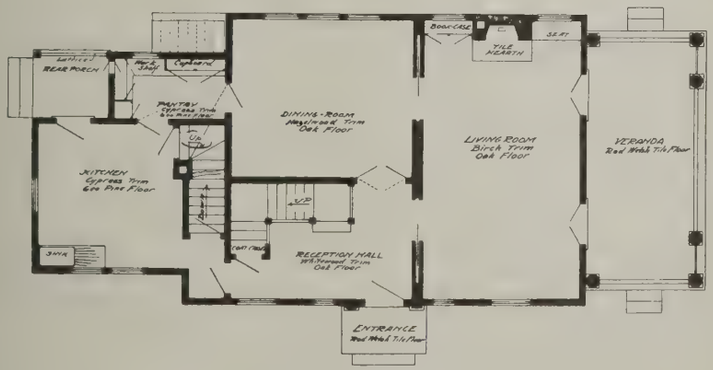
duced by the double glass door opening from the hall after the French window style.

The kitchen is very nicely arranged and is easy of access either from the dining room, reception hall, basement or servant's room. From here, there is a rear stair to servant's room on second floor. This service end of the house is trimmed with cypress finished natural and the walls are covered with "Sanitas."

The pantry provides cupboards, workshelf, flour bin, broom closet, and refrigerator and there is also a large window for light and ventilation. The trim here is cypress finished natural, also papered with "Sanitas" as in the kitchen.

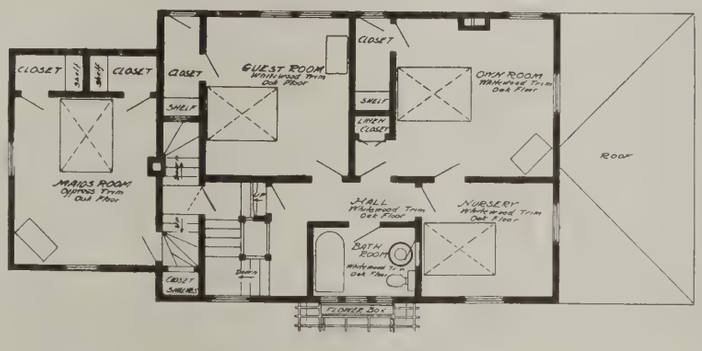
The floors in reception hall, living room and dining room are white oak; in kitchen and pantry, Georgia pine. The rear porch opening off the kitchen has one side latticed full height. There are also openings to pantry for milk and to refrigerator for ice, so that these can be attended to from the outside.

The basement is reached from the rear hall, also by means of an outside hatchway and in it are found a laundry with soapstone tubs and other conveniences, a cold storage room for fruits, etc., hot water heating apparatus, and fuel room.



The main part of the second floor consists of three bedrooms, hall and bathroom, all of which are treated with white wood trim, which is white enameled finish. The doors are all finished in mahogany. The floors of hall and bedrooms are all white oak. The bathroom has a white tiled wainscoting and floor and is finished with porcelain fixtures with exposed nickel plated plumbing. A medicine case with plate glass mirror in the door is built in the wall just above the lavatory. The walls are all covered with striped wall paper in Colonial effects. The front and side bedrooms have each long clothes-presses fitted with shades.

The servant's room is over the kitchen extension with the rear stairs leading directly to it. By this arrangement the service end of the house is isolated from the living quarters of the family. This room is large and comfortable and has cypress trim finished natural, also white oak floors, is papered in striped Colonial effect paper and has two large clothes-presses opening off it. The attic is unfinished, but has ample space for two large rooms.



This house is built in Rochester, N. Y., for Mr. Charles Wm. Eldridge, architect, from plans of his own, as described above. It is 24 feet, 0 inches by 33 feet, 6 inches, with a kitchen extension 12 feet, 6 inches by 18 feet, 6 inches at rear, has hot water heat, tiled bathroom, guaranteed plumbing, combination gas and electric fixtures, range, shades, cement walks, etc., and was built for approximately $5,600.

Charles W. Eldridge, Architect — Rochester, N. Y.

DEVELOPMENT OF GASOLINE ENGINES

By JOSEPH C. RILEY

ASSISTANT PROFESSOR OF MECHANICAL ENGINEERING, MASS. INST. TECH., BOSTON

Presented before the Congress of Technology at the Fiftieth Anniversary of the Granting of the Charter of the Massachusetts Institute of Technology.

* * *

(Continued from August.)

WITHIN the past three or four years special indicators capable of producing satisfactory results at 1000 revolutions per minute and upwards have been used in research work in a few technical schools and private testing laboratories. The instruments of Nagel, Watson, and Clerk and the Hopkinson indicator, are all of the optical type. They cannot be handled successfully except by skilled observers; in general they could not be used at all with the engine in actual service. The cylinder must be mounted on a rigid testing block and studied under artificial, ideal conditions. The data thus far available from such tests are merely fragmentary, but they are promising, and in time will surely be valuable. Conclusions drawn from a few isolated tests are not of much assistance. A series of tests is required, systematically conducted, with gradual changes in the one condition whose effect is to be studied and practical constancy of all other conditions affecting the result. Such investigations require a laboratory equipped with a good dynamometer and the best apparatus that can be devised for indicating and controlling the operation of the motor. Satisfactory dynamometers of the electric cradle type and also the hydraulic type are used by many engine builders as well as by the technical schools and automobile club laboratories, and much has been learned about the brake output of engines throughout the entire range of speed. What happens inside the engine cylinders, however, is not so well known.

Little improvement in power can be expected from the best engines; they are already excellent. There are automobile and marine motors today, of the four-cycle type, that give mean effective pressures from 87 to 95 pounds, based on the brake horsepower, even when driven at extremely high speed. This corresponds to gas mean effective pressures close to or exceeding 100 pounds, figures which would be considered good even for moderate speed stationary engines. On the other hand there are four-cycle engines of the same size that develop only 65 pounds mean effective pressure based on brake output. Of small two-cycle marine engines the maximum M. E. F.'s on brake output range anywhere from 70 to less than 50 pounds, depending on how well or how badly the fuel charge is supplied, exploded and rejected. The three kinds of two-cycle motors on the market, namely the three-port or valveless type, the two-port-with-automatic-inlet-valves, and the two-port-with-mechanical-inlet-valves have intrinsic differences in power which are not generally appreciated by the men who use these engines. The energy wasted in getting the charge into a three-port engine, or in dragging it into the crank-case against the pressure of a check valve with too tight a spring, and then blowing it into the cylinder after needlessly high compression, materially decreases the horse-power output. In some of the poorer engine equipments, the entering charge is further obstructed by insufficient passages through the carburettor; the charge is not merely throttled, it is fairly strangled; the wonder is that it gets in at all. Crank-case diagrams from such engines would set the designers to thinking.

Between the better and the poorer designs of gasoline engines there are wide margins in power, to say nothing of fuel economy. The dynamometer tells us that they exist and that the better results are well worth striving for, but it does not show whether deficiency in power is due to constricted passages, defective ignition and combustion, or any other definite fault. Now the scientific way to remedy a defect of any kind is to begin by investigating first its magnitude and then its cause; and the instrument adapted to such a study in the case of the gasoline engine is the indicator—in the half-size pattern, within limits, and then in the optical type.

With all fast running reciprocating engines the necessity for arranging the cylinders to secure regularity of driving effort and for balancing the moving parts to prevent excessive vibration is apparent. Good mechanical balance is particularly desirable for the class of engines discussed in this paper, because the total masses corresponding to a foundation are very light, and the services in which the motors are employed are such that vibration cannot be tolerated. The best engines for automobiles, boats and aeroplanes give evidence of having been planned by men trained in the principles of dynamics, as well as in all other elements of mechanical design. Some builders, however, have but hazy notions on methods of balancing. In fact, they seem to associate vibration with the sudden rise in pressure due to explosion within the cylinder, as if the shaking of the frame were due to the shock of explosion. That vibration results from motion of the masses, and that it would be practically the same even if the cylinder heads were removed and the engine were motored around by power supplied at its shaft is a new idea to them. Examples are common of this lack of appreciation of physical principles among men whose knowledge and experience in all other branches of design and operation of small engines is very broad. For instance, a certain motor was recently built for aerial propulsion, with an arrangement of cylinders making it virtually impossible to secure good balance or a good sequence of explosions. On trial, much to the builder's surprise, the engine shook so that it could not safely be driven at rated speed even on a heavy testing block, let alone upon the light framework of a flying machine.

Crank-shafts for six-cylinder engines of the four-cycle type are built with cranks in three pairs at 120 degrees; and a particular arrangement of pairs is chosen, resulting in a favorable order of distributing and firing, and giving almost perfect balance. In a certain instance, however, failure to realize the forces involved, combined with a fancied advantage to be gained by a different crank sequence, led to the design of a shaft for a large engine, in which the cranks were not correctly paired. As a result, the best possible order in which the cylinders could be set to draw and ignite their charges was unsatisfactory, and the engine shook so badly that a reduced speed was necessary until finally a new crank shaft had to be obtained.

There are many problems which arise in the design of machinery which cannot be solved even approximately until after the machine is built and tested. The experience gained by operation of the first few imperfect machines then furnishes the information required for modifying and improving existing forms, in varying sizes and powers, and thus the machine is gradually perfected without the application of purely theoretical reasoning. This was the case with the steam engine. Nearly all the radical improvements were invented and used long before they were systematically tested to find out just how efficient they were or how they could be made to give better results. This history is being repeated in the development of gasoline engines. The application of scientific methods of investigating them is only just beginning.

CONCRETE IN HOUSE BUILDING

By JOHN UPTON

LET us suppose that we are to erect the forms for a cellar wall eighteen inches thick, for a house 24 x 30 feet. We will assume that the wall is to be seven feet high and that the excavation has been made about three and one-half feet deep with straight sides and square corners; the earth being fairly solid. Of course in a sandy soil this would not apply.

The sides of the excavation being sufficiently straight and true so that outside forms are not needed for the lower half of the wall, the first step is to erect those for the inside. Begin by nailing a short piece on to two boards so that they make one board just twenty-one feet long, this being the length of one end of the inside. Place this at one end, eighteen inches from the bank and drive some stakes in the ground to hold it. Do the same at the other end. The sides must be cut as much shorter than the wall as the thickness of the ends. Assuming that inch lumber is used, cut them in this case thirty (30) feet, less three feet two inches, equals twenty-six feet and ten inches. Put the bottom boards for the sides in place, fastening them by stakes, then see that these boards are level and

that they form a perfect rectangle; that is, have four square corners. In case there are projections for bay windows or a cistern, the forms for these should be commenced at this time.

After making sure that all sides are correct, the boards level and the corners square, you should erect the corner studs, 2x4s or 4x4s, and fasten them by stay laths. Studs should then be set up along all sides. These should reach to the top of the wall and no harm will be done if they come above. The distance apart will depend somewhat on the material used, two feet is generally about right for two by fours used with inch boards. Heavier material can be used and the studs set farther apart. It is not necessary to nail the boards much, as the concrete tends to hold them in place rather than to force them out. After a few boards are on, a line should be stretched at about eight inches from the corners, and the work trued up by measuring from this line. Now is the time to fasten the bottom of the studs and do not be afraid of overdoing this for there will be considerable pressure on them and unless they are well secured, they will start toward the center of the cellar and the wall will become quite thick on the bottom.

One good way to fasten them is to run a stick of 2x4 or a board right across the cellar from one side to the other. Another way is to put a 2x8, 4x4 or similar stick on the inside and drive stakes down inside of this, then running some sticks across also. But in whatever way you fasten them, be sure they are all well secured at the foot; above this they will be wired to the outside forms and there will be as much pressure one way as the other.

In this case, where it will be twenty feet and two inches between studs; sticks twenty-two feet long could be used by letting one end go against the bottom of the stud and the other end come part way up on those on the other side. Continue the boards about half way up and then after raising the guide line, put in some braces to hold the studs. These braces may be fastened to stakes driven in the ground and can be just the proper length to meet at the middle of the cellar. If so, they should rest against a timber so that great pressure on one would be resisted by two or three on the other side. Another row of braces should be put in, at, or near, the top of the wall and there should at least part of them be nailed so as to hold as well as thrust so that the forms neither go in nor out. Sometimes it will be desirable to start filling the forms before they are entirely up, but generally, when they are put up in this way the entire inside forms can be built before any concrete is placed. In case concrete is being placed before the forms are all up, even more care must be used in bracing than would be needed if the inside forms were partly held by the outside ones.

The boards on the inside forms may extend a few inches above the top of the wall and need not be made level, but those for the outside forms should generally be so placed that they serve as a guide in finishing the top of the wall. This can be accomplished by putting them on level and if needed, ripping the last board; or they may be started from the top, although it is generally easier to space down and begin them at the bottom at the right height, filling any spaces there with short pieces.

If the inside forms should get out of position, it would not necessarily affect the work seriously, but the outside one should not be measured from them; but must be made the right length and with square corners, regardless of the thickness of the walls. Frames for doors and windows can be pieced out by nailing two by fours on their edges so that they fill the space between the forms. Spacers, or spreaders, should be cut the right length—the thickness of the wall—and put into the forms to hold them apart. Wires should be put through small holes bored or punched with nails each side of the studs. These should be about eighteen inches apart vertically, and should be twisted up taut.

BIRCH TIMBER

By WARFIELD WEBB

A FEATURE of the building industry that is worthy of more insight is that pertaining to interior finish. Perhaps there is no other portion of a structure, it matters not as to its nature or size, that has demanded more thought from both architect and contractor than the above theme. As we progressed toward a more beautiful and pleasing exterior, so have we come to view the interior of our buildings in a different light. Now we consider the most desirable materials and the most attractive method of making the interior one of real art.

Of the materials for this purpose there are many kinds. Of the lumber there are perhaps fewer kinds suitable for this work, and for this reason there must be more than passing consideration given these by the contractor. To be more explicit, there is in reality but a few kinds of lumber used for interior finish, in any but the most commonplace buildings. This list will include mahogany, red gum, oak, plain and quarter sawed, poplar, birch, maple, pine, cypress and a few others.

Of the list there is reason why the contractor should interest himself more fully in birch. What is most desired today by the average builder of home or office structure is neatness, reasonable cost and still a stock that will prove satisfactory. Mahogany is too costly for the majority. Quarter sawed oak is likewise. Plain oak, maple and pine have all been used to excess. In the demand for some other kind of stock that would meet all the requirements, and still be reasonable in cost, the lumber manufacturers have found birch to be the wood that is possessed of many admirable qualities.

Of birch there is much to be said. Its uses date back for many years, and its purposes have been multiplied so that today this wood is used for a number of varying purposes: Furniture, cooperage, ship building, flooring and interior finish. Birch veneers are increasing in demand, and the number of birch veneered doors is one of the notable features of the industry. Then there are several kinds of birch wood. The ordinary kind is called common birch. The trees attain a growth of from sixty to seventy feet, grow rapidly, and the tree is from 1½ to 2 feet in diameter. The bark is smooth and silvery white. Even the bark is put to many uses. Not varying very materially from this is the black birch. This is more valuable than the common variety, and is used for a higher class of work. Yellow birch is used mostly for ship building, while sweet birch or cherry birch, as it is called by some, is used for interior finish and flooring more than any other species. The wood is tough, fine grained, and very durable.

Much of the birch lumber has a very pretty figure so that when it has been properly finished and stained, it will readily pass for mahogany. In fact, a good imitation mahogany of birch will deceive all but those who are experts in detecting the difference. On this account, there has been an increasing demand for the wood for this purpose. Many who cannot afford mahogany will select birch stained to resemble it, and there is practically the same effect obtained. It is sometimes simply finished in the natural wood, and makes a most pleasing style of interior decoration.

Birch can be compared in price and in some other respects to plain oak, or a good quality. It is equally as hard and when properly kiln dried will make a most excellent wood for flooring and all kinds of interior finish. If it has not been well dried out it will warp, and therefore the importance of this is easily understood. For the manufacture of furniture birch has been a standard for years. Only within a few years has it become so popular as an interior finish. This was partly due to the fact that the demand for varying kinds of interior finish was not so urgent and because it was not generally known as a desirable wood for this purpose. Within the past few years its gain has been steady. Now the architects specify it on many costly structures, and it will grow in favor in the future. While not as desirable for flooring purposes as oak and maple, not being quite as hard as either, it makes a most pleasing floor.

It is a very durable wood. Its compactness makes it comparable with the better grades of hard woods, and for this reason, and that of its price and the possibilities of its finish, have forced it prominently to the forefront. The average constructor of buildings today desires to make his abode as attractive as possible. Nothing adds so wonderfully to a structure as a pleasing interior, and this of some style of wood, often in the natural color. There is a growing desire always for something just a little different, and the average builder is desirous of noting this fact, especially when the cost is nearly the same as soft woods.

Somehow birch seems to fit in this nook most admirably. We have seen so much oak and pine and poplar and other kinds of interiors that the newer style of finish will not be unwelcome. For birch there is a pleasing future. It has the durability, the quality, the finish and the surface to make it a desirable wood for all kinds of interior work, even where there is more than ordinary art demanded.

BRICKS AND THEIR HISTORICAL INTEREST

By H. T. F.

IN THE antiquity of the brick as a building material it is needless, nor is it indeed our intention, to insist. The great national collections of Europe, the British Museum foremost in the number, shows us bricks, sun dried and backed, from the ruins of Nineveh, and from the days of that city to the present moment bricks have never ceased to be an important material in the hands of the builder. That throughout Asia Minor they were largely employed we have seen, only very recently, shown in these columns. M. Rayet, in his work on Miletus, shows that the far-famed palace of Croesus was built of no more costly material than honest bricks. What these bricks were, and their quality, are even to this day appreciated by the natives, who for many centuries, have plundered the ruins to build, or to patch up their own even more ruinous houses. The use of bricks among the Romans, who largely employed them as building materials, as we see in the familiar instance of the Temple of Concord, has been more than once the subject of the inquiry of industrious antiquaries, for the Romans were not content with producing the flat, tile-like brick which is so often to be met with in the lower portions of antique structures scattered over the Empire, and that are known in England, but their bricks were indelibly stamped with the mark of their maker, the names of the reigning consuls, and sometimes the year. From this source, then, more than one patient archæologist has gathered a rich store of information. But few inquirers have ventured far on the apparently arid and difficult road, which has hence remained less explored. Some curious information has, however, been lately thrown on the question by the researches of the French antiquary, M. Descemet, who has published in a recent number of the Bibliotheque des ecoles d' Athens et de Rome—an excellent publication, founded in 1877 and now at its seventeenth number—an article on the "Inscription doliaires latines" on Roman brick-marks, more especially relative to the gens Domitia, in antique Rome the most renowned brickmakers.

From an epigraphical point of view the brick marks of the Romans have aroused the attention of more than one archæologist, but the difficulties which have stood in the way of procuring the stamps, added to the enigmatical nature of the inscriptions themselves, have led the inquirers to fields where the results were more showy and more easily obtained. M. Descemet has long been known to the antiquarian world: as far back as 1857, his "Fouilles de St. Sabina," attracted no little attention, as also, in 1876, his study "Sur quelques Regels de Briques antiques," published in the Bulletin de Correspondence Archaelogique. In possession of a valuable collection of stamps of his own, together with copies from the brick stamps of the Vatican Museum, M. Descemet had at his disposition more than ordinary sources of reference, and the result of his study has been the work the title of which is above given.

The Italian antiquaries of the seventeenth and eighteenth centuries, Nardini, Ciampini, and their contemporaries, had not largely drawn on the store of historical information afforded by the Latin brick inscriptions; Fabretti was, indeed, the first to set into any order the more remarkable of these, but his efforts were merely tentable; his collection of inscriptions was unclassified and incomplete. It was reserved to the worthy Abate Gaetano Marini, the curator of the Vatican Museum, at the close of the 18th century, to put together in a methodical manner the stamped bricks of the choice collection under his control; this task he admirably performed, preparing a learned catalogue which, however, remained at his death in an incomplete and manuscript form; but, such as it is, this manuscript preserved in the Vatican library, has proved a mine of information to all subsequent writers. Marini's catalogue was arranged with admirable order and carefully classified, each brick of the collection being the subject of numerous commentaries.

In spite of Marini's method, M. Descemet has adopted another system more suited to the requirements of the day, as rendered necessary by the considerable addition made to the list of brick inscriptions since the recent excavations. In his introduction, M. Descemet has carefully shown the importance of the study of these brick inscriptions by which the date of the erection of a building may be approximately ascertained. But as the author hastens to add, the fact of the bricks bearing dates, or stamps being found in certain spots, is not, of course, conclusive evidence to the archaeologist. Thus, in 1844, at Aix, in Provence, a brick of the year 123 was found, stamped with the work of a Roman workshop, but the presence of this brick can alone be accounted for by the effect of accident, as it was scarcely possible that a town near Marseilles, so long famous for its pottery, should receive the bricks from Rome. On the shores of the Adriatic, at Pola and Zara, and in other towns of Istria and Dalmatia, the existence of a large number of bricks bearing the stamp of Rimini would tend to show that the brick trade, which still exists on both sides of the Adriatic, can be traced back at least eighteen centuries.

But apart from the geographical information these stamped bricks afford, the inscriptions they bear throw not a little light on an ill-known state of Roman society—the education of the slaves, who though we have classic evidence proving that they were placed under schoolmasters, would seem to have little profited by their education, as the inscriptions it was their duty to stamp could only have had their letters placed upside down or transposed (as they are often found), by persons unable to read, who copied as well as they could a model under their eyes.

How these stamps and brick inscriptions were made is a point of some uncertainty. Had the ancients moulds, or did they use movable type? This latter method would suppose a great invention of the fifteenth century to have been forestalled. M. Descemet, who devotes some pages to the discussion of the question, concludes in favor of the moulds, such as we see examples of in more than one national cellection. The stamp was cut in relief, or incised, and then—like the butter-print of the present day—made use of. As for the character of the spelling to be met with, this would naturally arise from the want of education on the part of the workmen.

Among the various other points considered by M. Descemet, the reason why the Roman bricks bear the date of their production is not the least curious; but when Pliny's advice to the architect is remembered, only to make use of the bricks when two years old—"aedificiis nonnisi bimos probant,"—an explanation may perhaps be found. A point has been omitted by M. Descemet—to one of which attention is drawn in a recent able article in the Revue des Questions Historiques—in his neglecting to refer to the palms, pine cones, and animals so often found stamped on the Roman bricks. It is now known that with the potters whose name represented or recalled any object or animal, this object he stamped on the pottery or brick of his make. Thus, where we meet with the stamped images of a wolf we may be sure that the workman's name was Lupus.

As the title of the work shows, it is alone to the brick inscriptions relative to the gens Domitia that attention has been paid. Why this gens has been chosen the author explains. It would appear that the gens Domitia possessed the largest and most important of the brick manufactories of ancient Rome; in the person of the virtuous Marcus Aurelius, it ascended the imperial throne. From the brick inscriptions gathered, the wealth of the emperor would appear to have been enormous, as we learn by the large number of workshops his gens employed, in company with those of the gens Aria which he inherited through his marriage with Faustina.

The interest of this quiet and apparently little-inviting study would be thus seen to be great. Its historical value is no less appreciable. We are comparatively far from the days when the history of ancient times was merely gathered from former texts; the aid afforded by numismatics and epigraphy is largely called into requisition by the more serious modern historians. This little work of M. Descemet shows us how, even from the humble sources of the brick inscriptions important facts may be gathered. The careful and beautifully cut Roman stone inscriptions, so easy to read, are not sufficient; the research can be carried further, as we see for instance, in the study by M. Dumont on the ceramic inscriptions of Greece, and even more strikingly in the delightful study which M. Dressel published some time since on the shattered débris of Monte Testaccio. M. Descemet's inquiry into the brick-marks of ancient Rome has already yielded some curious information; it is to be hoped that his success will encourage him to further study in this yet far from exhausted field of archaelogical research.

PAINTING TIN ROOFS

By A. ASHMUN KELLY

Much has been said concerning tin roofing, defects of manufacture have been pointed out, and the causes of tin roof deterioration, particularly as regards the painting thereof, have been discussed until there would seem to be nothing more to discuss. Yet it is evident that there has not been a right understanding of the matter, nor a correct knowledge of the true cause of tin roof failure, even though experts have told us all about it. First, then, let us ascertain why tin roofing does not wear as it formerly did. This point I believe is well settled, in the fact of the newer method of sheet iron manufacture, whereby the product inclines to rust, no matter what paint may be used upon it. It is well known that sheet tin will rust under the best paint, and in the absence of all the usual agencies for iron deterioration, such as vapor, or dampness, and so on, under the tin roofing, and while the surface tin has been well painted. That rusting will go on, in spite of anything we can do. Some tin will stand up longer than certain other tin, this due to quality, which is governed by price.

It being settled, then, that tin roofing will rust in defiance of any paint or care, let us see what can be done to make the surface resistant to the weather, etc., as long as possible. Taking a new roof we may find it damaged by scratches from the shoes of workmen, and here the rust will start first. The paint then should be applied as soon as possible, before rust starts. Many say that a new tin roof should stand until it rusts slightly, which will give the paint tooth or holding surface. This is a grave error, as the rust will continue under the paint.

The working specifications adopted by the National Association of Master Sheet Metal Workers call for the cleaning off of the surface and immediate painting. The under side is to have a coat of paint, kind not stated, before laying. The paint for the upper side is to be of pure metallic oxide of iron, or Venetian red, mixed with pure raw linseed oil. No driers or turpentine to be used in this paint. The paint is to be applied by hand, with an ordinary paint brush, and the paint is to be well rubbed in. Two weeks after the first coat give a second coat. A year later apply a third coat. Some advise two coats of paint on the under side, and no doubt the extra cost would be amply repaid in the longer wearing of the tin roof. Tin roofers, as a general thing, paint the under side with a thin mixture of asphaltum and benzine, and they might as well use whitewash, for all the good the cheap benzine mixture does.

Asphaltum is injurious to tin roofing, and it is advised never to use any paint on a tin roof that contains tar, pitch, or bituminous compounds. This point has been tested by the Association of Sheet Metal Workers.

In mixing roofing paint it is better to use raw linseed oil than the boiled oil, excepting in the case of graphite paint, when boiled oil will be found better suited.

Regarding painting an old tin roof, first let the tinner repair any possible damages. In case this is not done, or cannot conveniently be done, then scrape and clean the tin, and where a leak is found or suspected take a strip of linen toweling and dip it in the paint, and lay it smoothly on the broken part. Then paint the roof with a good paint, iron oxide or graphite, as desired. Linen material is advised in this method, for the reason that cotton will rot from the action of the oil, while linen will not.

If a tin roof can last from 30 to 40 years, as it did in times past, it might safely go without paint for a long time. Many an old tin roof has gone without painting for intervals of six to eight years. It has been said by some one that the interval between painting an old tin roof is about equal to the average life of a tar-and-gravel roof, but such endurance cannot be looked for from ordinary modern tin. Good, hand-made tin has stood exposure on roofs for years without paint, and without showing any rust. As a matter of fact, tin itself cannot rust. Still, it is best to paint a tin roof.

The proper paint for tin roofs, old and new, is that made from metallic brown, or oxide of iron, Venetian red, or silica-graphite paint. Each has its champion, and all are good. Paint the roof as soon as possible after it has been laid. Give it two coats, with a week between, and after the lapse of two or three years, depending upon local conditions, apply another coat, always using one kind of paint.

A writer says he knows of nothing better than red lead ground in raw, cold-pressed linseed oil, applied the day it is mixed, which is a wise precaution, for red lead settles in the pot quickly, and should be used dry, and be mixed just before beginning the job; if ground in oil, as the writer describes it, it would be hard and difficult to mix. For this reason red lead is very seldom bought ready ground or mixed. He states that after painting a roof with the red lead he applied iron oxide paint, being persuaded to do so, he adds, with the result that the brown paint peeled, and even the red lead paint came off in places. Doubtless the brown paint failed to hold on the hard surface of the red lead paint. I would not advise the red lead priming coat. There can be no advantage gained over the use of a simple iron paint.

As to silica-graphite paint, a master painter tells me that he did a tin roof with it, and that it did not require repainting in 18 years. Another painter calls attention to a roof that he painted with the graphite paint, and after 12 years it looked good and apparently would not need repainting for several years more. This paint has been known for many years as a roof paint, it having a strong affinity for iron and adhering well to tin. Being a carbon, it would naturally protect the tin from rust, whether from water or from air. It may cost a little more, but as it covers more surface than mineral brown paint, pound for pound, to the extent of 58 square feet, and wears probably five times as long, its economy is apparent. It sheds water like a duck's back, and is not affected by heat, cold, acids, alkalies, or any known chemical solvent; it fuses only at a blow-pipe heat.

But there are many testimonials also in favor of the oxide of iron paints, such as the well-known brown and Venetian red. Tin roofs are known to have stood as many as eight years without repainting, after being done with brown paint. But it must be remembered that a roof may seem to be in good shape as regards the painting, and yet not be. Here is where some make a mistake, and rush into print with it. The roof ought to be carefully examined, in various parts of the surface, and its true condition noted. I make these remarks in view of the conflicting testimonies of painters upon this subject.

Some of the oldest and most expert painters prefer Venetian red paint for tin roofs. There are at least two kinds, one a pure iron oxide, and the other having a base of gypsum, which is made red with a pure iron oxide of a bright color. The English Venetian red is generally supposed to be the best of the class. Red lead may answer, but it is costlier than the browns and harder to mix and apply. In the thinning of red lead paint some advise linseed oil and turpentine in equal parts, while others use two-thirds turpentine. This is claimed to form a hard and durable cement.

Never place tarred paper under tin roofing. It will surely corrode the tin. Sheathing paper is all right.

Whatever kind of paint you may use, see to it that the tin is perfectly dry before painting, and if the work can be done in the early fall, in dry weather, it will need no driers in the paint, and the work will last much longer than when done in warm or hot weather. The best work can be done with a round paint brush, not with a wide brush fixed to a pole. Get down to it, rub the paint in and brush it out evenly. Avoid runs along the seams, as a run or excess of oil in any place will eventually cause the paint to peel off. Be sure that every part is perfectly coated.

An inexpensive paint may be made for old gutters, etc., by the following method: Place all the old paint skins, the cleanings from paint pots, bits of dry putty, and any old paint on hand, into an iron kettle with some raw linseed oil, and boil the mass until all is dissolved. Then strain, and add fine dry sand until the mixture is about like average paint consistency, so that it will spread well under the brush. It is best applied hot, or at least warm, and a quite heavy coat should be given. It can be used around flashings, chimneys, etc. When dry it has a hard, enamel-like surface, and it may be colored to suit any surrounding color. If it has been properly prepared it will be as smooth as glass.

Mrs. Newlywed Again

Mrs. Newlywed(to clerk)—"Have you any wax for polished floors?"

Clerk—"No, we only have sealing-wax."

Mrs. Newlywed—"Well, that will do. If it's for the ceiling, I suppose it will do for the floor just as well."—Suburban Life.

A BUILDER'S COURSE IN ARCHITECTURAL DRAWING.

RALPH F. WINDOES.

WORKING DRAWINGS

BEFORE the student makes a working drawing there are a number of things that he must understand and apply to his work, some of which will now be given.

The first floor plan is generally the first to be drawn as it is, without doubt, the most important floor of the building. The second floor and the basement are easily worked in after the first is completed.

WALLS.—In laying out any floor plan, first draw the outside walls complete, regardless of door and window openings. In a frame building such as we have taken as an example, these are drawn 6 inches thick. The inner partitions in this case are the same, but where sliding doors are used the partitions are 12 inches thick.

STAIRS.—After the walls are drawn in to scale the stairs should be planned. They are a very important part of the building and great care should be taken with their design. That no terms may be used that are unfamiliar to the student, a few definitions will be given.

The TREAD is the top of a step.

The RISER is the vertical face of a step.

The LINE OF TRAVEL is the path that a person would naturally follow when using the stairs. It is within easy reach of the handrails or the walls, about 18 inches, and its length is the run of the stairs.

The RISE is the whole height of a flight.

WINDERS are the steps where the stairs turn. The treads on the line of travel on winders must be the same width as the treads on a straight flight.

The height of a riser must be an exact divisor of the rise of the stairs. We must know the rise of the stairs in inches and divide this number by an assumed height of the riser. This gives the required number of risers. For example, let us consider the house we are planning. The rise here from first floor to second floor is 10 feet, or 120 inches. Let us assume 8 inches for a riser height; 120 divided by 8 gives us 15, the number of risers. This would give us 14 treads to plan on.

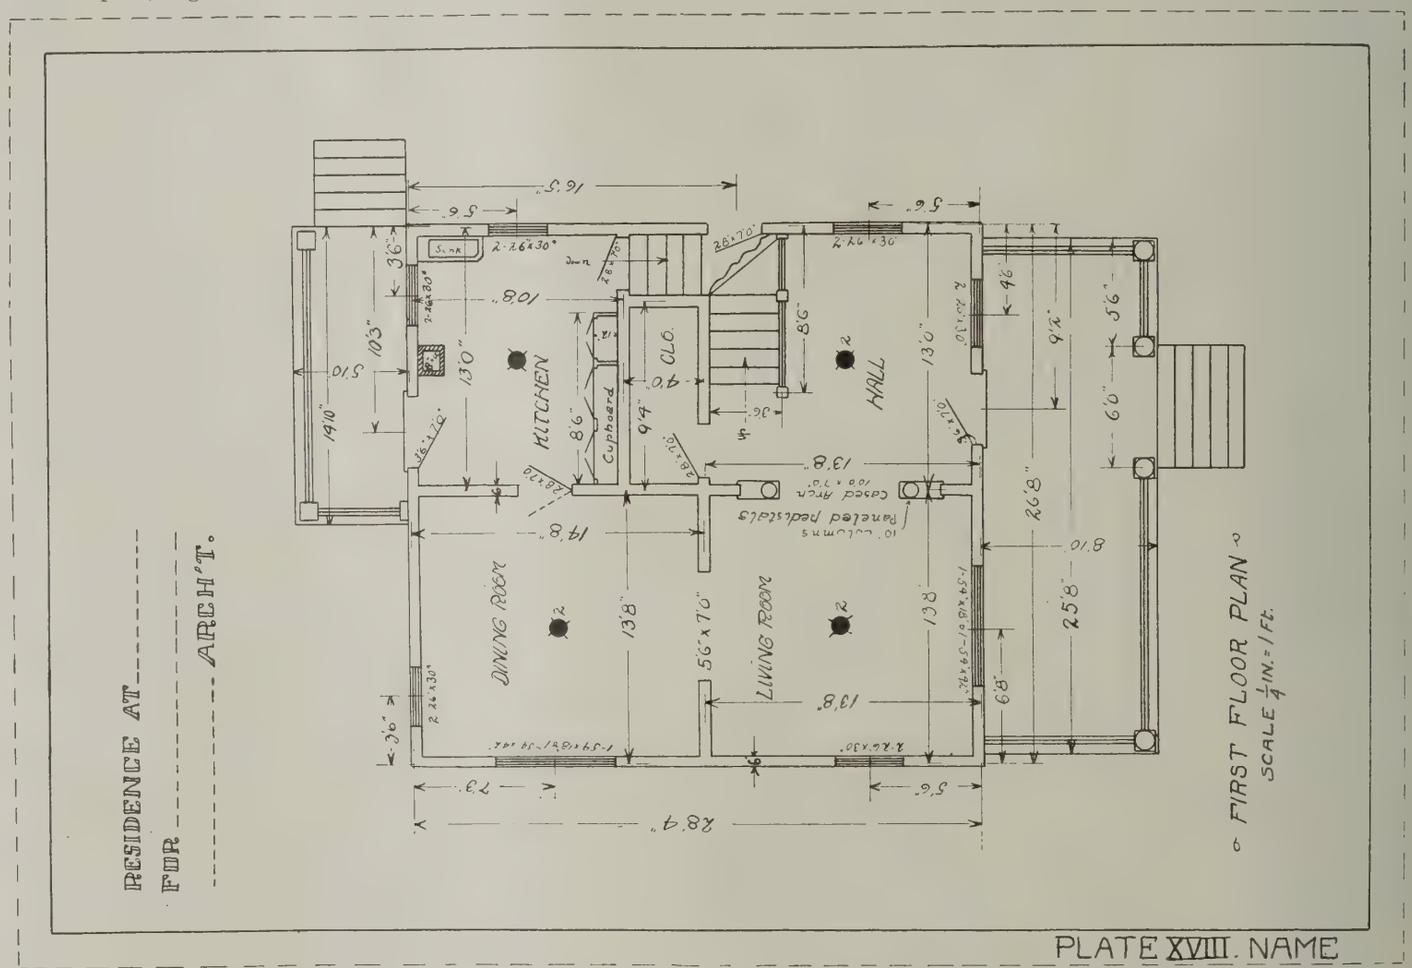

PLATE XVIII. NAME

As was stated in a previous lesson, the treads must be in proper proportion to the risers. With an 8-inch riser such as we have used, a tread of about 9½ inches will make an easy traveling stair, as the sum of the two should be 17 or 17½ inches.

For cellar stairs limited space may require the risers to be higher and the treads narrower than on the main stairs.

To lay stairs out, first lay down the travel line. Lay off on this the exact number of treads, to scale. The travel line in our problem is nearer the inner wall than to the handrail. Remember that the tread on the winders must be the same as on the straight flight.

In planning stairs care must be taken to supply ample head room for the flight by figuring on the overhang of the upper floor.

WINDOWS AND DOORS.—Next, plan the wall openings. Be sure, if possible, to have these, on the different floors, centered on common vertical axes, or the exterior appearance of the building will be bad, even though the openings be unlike in width. Do not

have too many different sizes of windows, as this brings the cost of the building up. Exterior doors should be wider than interior, at least 3 feet wide. A swinging door should be used between the dining room and the kitchen. All door swings should be shown on the plans. The opening on our plans between the living room and the dining room should have a sliding door, or doors, if used in a higher cost building. The cased arch shown consists in a wide opening with two columns supporting the arch. It should be shown in detail, as will be explained later on in the course.

CHIMNEYS.—The chimney interior should be 8 by 12 inches for the heater and the range. This is also the proper size for a fire-place flue. The walls of the chimney may safely be 4 inches thick. It is a good plan to use flue tiling in all flues.

DIMENSIONING.—All floor plans should be completely dimensioned. The length and the breadth of the building all over should be given, the length and breadth of each room and the same for the porches. The center of each window and door on the outside walls should be located from the corner of the wall nearest to the said opening. The size of each window and door should be given on each plan. For example: a door marked 3 feet 6 inches by 7 feet 0 inches means a door 3 feet 6 inches wide and 7 feet 0 inches high. A window marked 2 feet 26 inches by 30 inches means two lights 26 inches wide and 30 inches high.

Notice that the arrow heads do not end on the wall line, but are about 1 inch inside of the outside of the wall line, and in the center of the partitions. The sill line of the house is about 1 inch inside of the outside of the wall line. The dimensions being given in this way, it is very easy for the carpenter to run his measuring stick between the outside studding and against the outside boarding, and to measure across, thus locating the center of an interior partition or the center of a window or door opening.

MISCELLANEOUS.—The cupboards, sinks, bath fixtures, etc., must be located and drawn to scale. Common cast iron kitchen sinks run in the following sizes: 16 inches by 24 inches, 18 inches by 24 inches, 16 inches by 30 inches, 18 inches by 30 inches. Bath tubs are about 30 inches wide outside, and vary in length as follows: 4 feet, 4 feet 6 inches, 5 feet, 5 feet 6 inches and 6 feet. Water closets take up floor space of about 2 feet by 2 feet 6 inches. Corner wash bowls about 16 inches by 16 inches. The ordinary oval bowls are 12 inches by 14 inches or 15 inches by 17 inches. The gas fixtures are located as shown.

PLATE XVIII. FIRST FLOOR PLAN.

If the student thoroughly understands the information given above, few directions need be given for this plate. It is advised that he draw a vertical and horizontal center line through the center of his working space, and lay out his dimensions from them. The scale given upon the plates here reproduced is the one by which the student is to work. All house plans should be drawn at a quarter-inch scale, with details at a half-inch, three-quarter-inch, or full size. Notice that there is a great difference between "quarter-inch scale" (¼ inch equals 1 foot) and "quarter scale," or one-quarter full size (3 inches equals 1 foot).

It is not necessary for the student to ink this plate in unless he so desires for the practice afforded, as he should make a tracing of it and all the rest of the working drawings he makes. But do not make the tracings until ALL of the working drawings are completed. Pencil drawings that are to be traced must be complete in every respect and drawn with a rather soft pencil, about a 3H or 4H. All working lines and lettering should be traced in with full black lines, but dimension lines should be inked in with red ink, but with black arrow heads and figures. From these tracings blue prints are made, which will be talked of later.

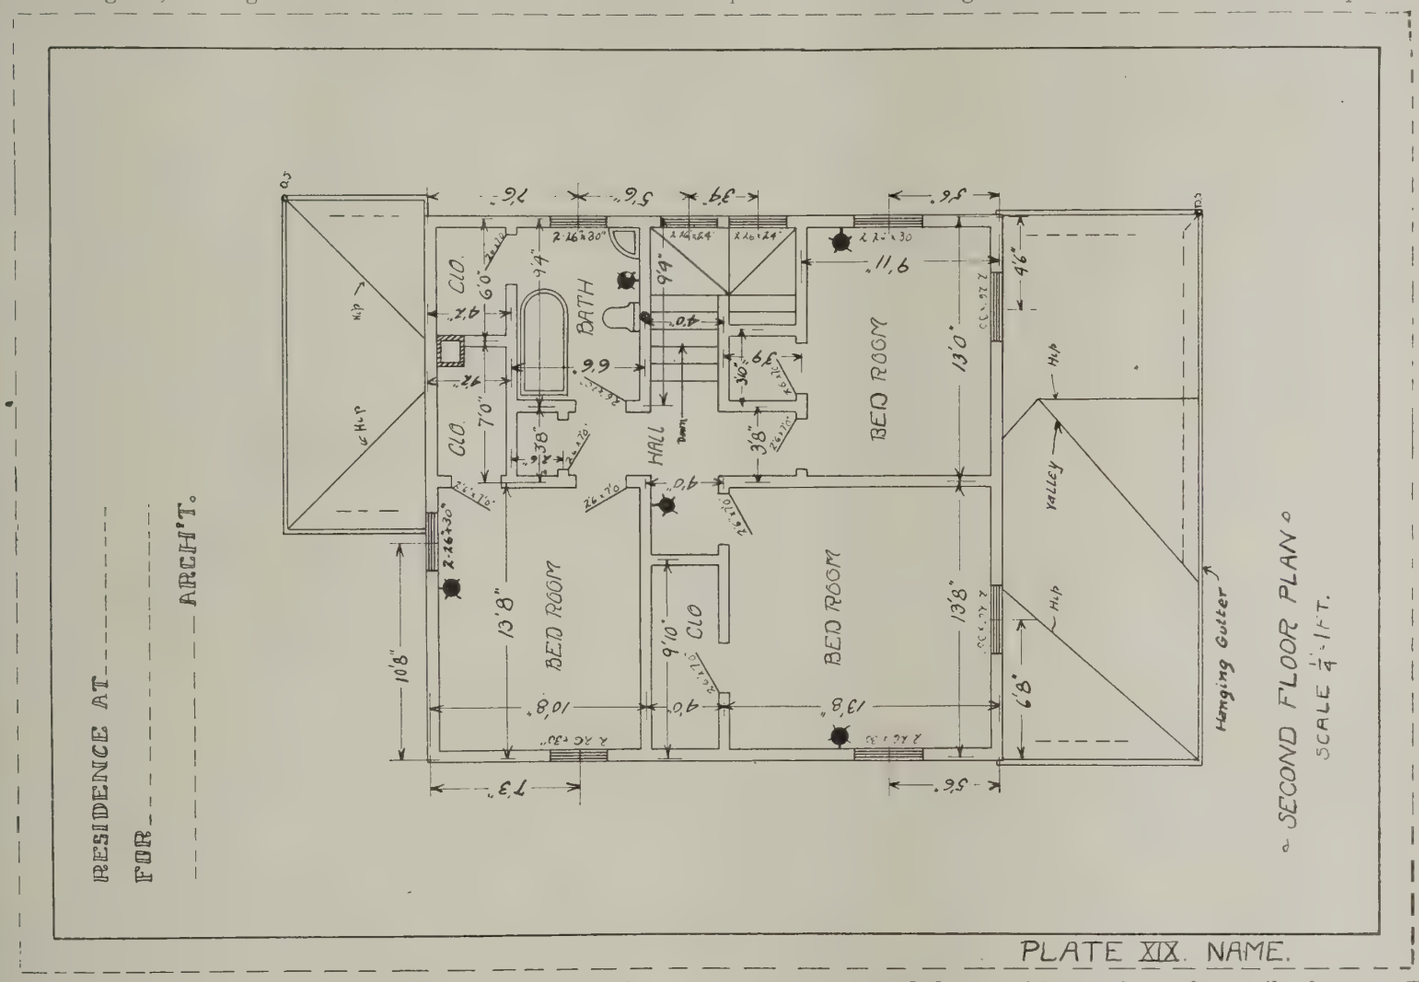

PLATE XIX. NAME.

PLATE XIX. SECOND FLOOR PLAN.

The outside dimensions of the second floor plan are the same as those of the first floor plan.

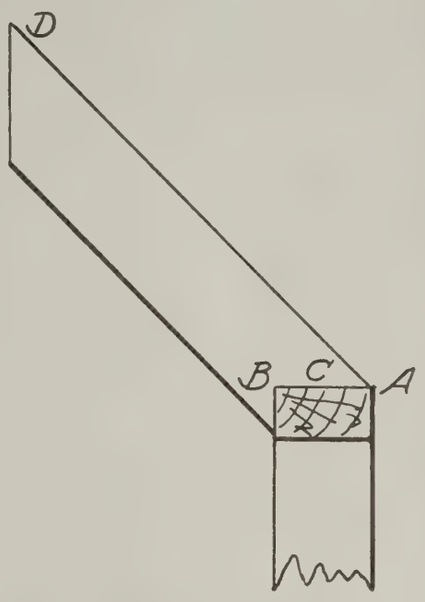
The main partitions should be directly over those on the first floor, if possible. Hall space should be provided so that all the bed rooms have easy access to the bath room and to the stairs.

The bath room is planned directly over the kitchen so that the service pipes may all be in the same part of the building.

Notice the small closet off the front bedroom on the right. It had to be cut off so as to allow sufficient head room to pass under. Notice from the first floor plan that this closet obstructs the view of four risers. This means 32 inches to take from the ceiling height of the first floor to give the proper amount of head room. The ceiling height is 9 feet 2 inches, which would leave 6 feet 6 inches for head room, which is ample. Of course, this was all figured out before the closet size was determined.

The roof plans of the front and rear porches must be shown on this plan. A hanging gutter is used on them and the down spouts should be shown.

(To be continued.)



OUR READERS' PAGES

[The Editor does not hold himself responsible for the opinion of correspondents. Short, crisp letters will be appreciated. To insure publication, the name and address of the writer must accompany the communication, not necessarily for publication. Sketches of work or methods will receive our earnest attention. These columns are open to our readers at all times without cnarge, and any questions or experiences will be given proper space.—Editor.]

ANSWERS

RAFTER NAMES.

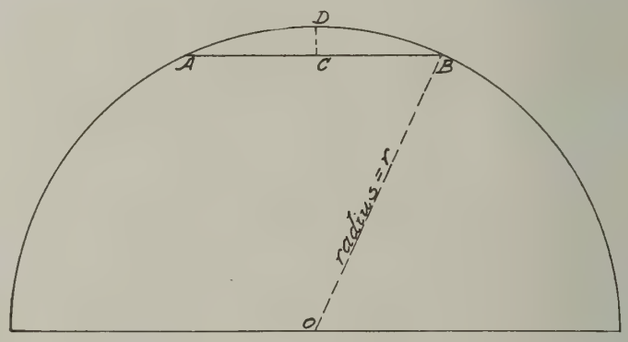
From F. T. H., in reply to L. M. H.

"A" is the toe, "B" is the heel, "C" is the foot and "D" is the point.

SILO DOORS.

In answer to R. R. D., Fillmore, N. Y., the following is taken from Bulletin No. 21 of the American Portland Cement Manufacturers: The cut shows an inside view of a continuous door opening in the concrete silo. Note the rods across the opening. The doors consist of grooved plank, resting in a rebate in the concrete walls, and depend on the pressure of the silage to keep them in place. It is to be noted that the doors must be air and water tight in order to preserve the silage.

SILO DOOR RUNNING FROM BOTTOM TO TOP.



In reply to V. A. McC., St. Ignatius, Mont.:

In regard to maple floors, the best way to nail these floors is to use 6d cut flooring nails, nailing about every sixteen inches. For the very best work it is advisable to bore a hole for the nails, as the kiln-dried maple splits very easily. Some grades of maple are bored at the mill. When laid over sleepers it is often necessary to cut every piece to bring the nail hole over the sleeper, or else bore them, but laying on under floors it is not necessary. For the best work the material is end matched. The flooring must be well driven up with a block and well nailed. The material should be selected and graded for color and length. For the best work the long pieces should be used in the center of the room, the shorter being used on the sides and ends. This applies particularly to ball rooms, etc. To prevent dampness, it is best to lay maple flooring over heavy rosin sized building paper.

LENGTH OF CIRCULAR ARCS.

From G. F. H.

In answer to the question from the "Young Bricklayer," of Dayton, Ohio, will say that there are two methods in finding the length of the arc of a circle; one when the angle contains degrees, minutes and seconds, while the other just plain English feet and inches, the language that nearly all bricklayers use in making their calculations.

Let us find the length of the arc in the illustration, taking for granted that the "Young Bricklayer" knows the length of the chord AB and the height of the segment CD. (If, however, he does not know the height of the segment when he has the length of the chord and the radius given, he may find the height of the segment by the formula $H = \frac{1}{2}\sqrt{4r^2 - c^2}$.)

Let r = radius of arc.

l = length of the arc = length of ADB.

c = length of the chord = length of AB.

h = length of segment = length of CD.

Then $l = \frac{4\sqrt{c^2 + 4h^2} - c}{3}$

Example.—If the span, or chord, AB is 6 ft., or 72 inches, and the rise CD is 8 inches, what is the length of the arc ABD?

Solution.—Here the span AB is the chord, and the rise is the height of the segment. Applying the formula,

$$l = \frac{4\sqrt{c^2+4h^2}-c}{3} = \frac{4\sqrt{72^2-4\times4^2}-72}{3} = \frac{4\times73.76-72}{3} =$$

74.35 inches, or 74⅜ inches nearly.

REMOVING PAINT.

From B., Chicago, Ill.

Regarding paint removers, Mr. A. A. Kelly in American Paint and Oil Dealer says: "There are several substances that will decompose oil, the principal ingredient in paint and varnish, but the trouble is that they contain alkalis, and hence are always more or less objectionable.

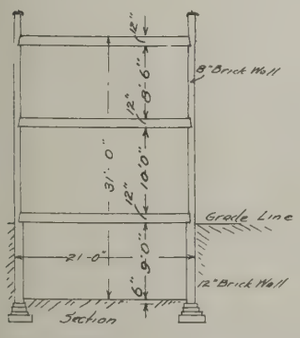
"Ammonia will do as well as potash and soda, and any discoloration may be bleached out with oxalic acid. Ammonia is especially useful on moldings, etc., as it will dry perfectly and not injure subsequent coats of paint or varnish. Soda and potash is apt to come through and injure the paint or varnish, if it is not thoroughly removed with plenty of water. Ammonia is also very good for removing old filler in hard wood.

"A very good emulsion remover may be made by adding one part of turpentine to two parts of ammonia, shaking the mixture well. The emulsion is permanent, and after being applied should have a few minutes to work, when the paint or varnish will be soft enough to be scraped or rubbed away.

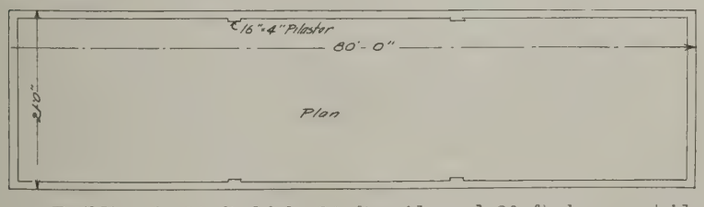
"To those who will use sal soda and lime, or potash and lime, or strong ammonia, I would say, be sure to use oxalic acid afterwards, as a bleach, and give it plenty of time to work.

"Here is another formula: Dissolve one pound of potash in three pints of water, and set on the stove to heat. Then add enough dry yellow ochre to make the mass like a roughstuff. Spread this on the old paint that you wish removed, and in a little time the paint will become soft enough to allow of easy removal by means of a scraper. After removing all the paint, wash off with soap and water, to remove all the potash. Let the surface of the work dry perfectly, then sandpaper it and give it a coat of clear linseed oil.

"Creosote or carbolic acid removers have a very objectionable odor, and cannot be neutralized, after using them as removers. That is, their effects cannot be done away with so that the subsequent paint will not be injured. They are also hard on the flesh of the workmen. Fusel oil or amyl spirit removers are objected to because highly inflammable, and injurious to the health.



"Alkalies, such as lime, potash, soda and ammonia, when used in their full strength, will injure the fiber of the wood, if in contact therewith. A little care when using them will result in minimizing this danger. The trouble comes where there are large joints or other open parts, into which any and all of these removers will go, and as they are hard to get out, the result is trouble after finishing up."



These preparations are for work on a large scale. Where only a small amount of paint is to be removed, any paint store will supply ready mixed remover, which will do away with the work of preparing it.

STRENGTH OF WALLS.

From J. G. C., Flint, Mich.

I shall be glad if through your paper you can say whether you consider the walls of a building shown in this sketch are strong enough.

Building is 31 ft. high, 21 ft. wide and 80 ft. long, outside measurement. It will have basement, store and workroom for upholsterer on first floor, with dwelling rooms on second floor.

At the front the grade line is at first floor level and at rear about two feet lower.

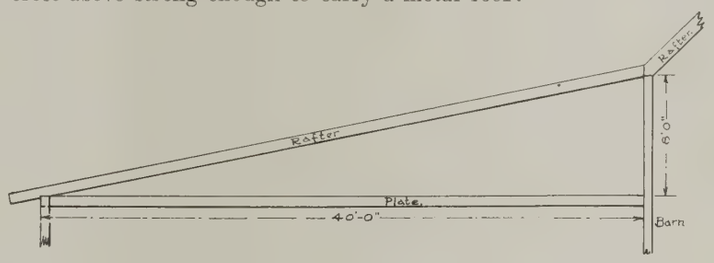
Walls to first floor 12 in. brick wall. First and second stories 8 in. Two pilasters as shown on each side wall, probably two of these will contain flues.

The joists to be 2x12-12 in. on centers. One text book shows New York allows walls of this thickness for building up to 35 ft. high.

QUESTIONS

GILDING AND BURNISHING.

From C. W. I., Chatham, Ont. Can you give me any information or instructions on burnishing? I have done a good deal of gilding but have never had any experience on burnishing.



CUTTING WINDOW OPENINGS.

From G. J. R., Syracuse, N. Y. I would like to see an article on cutting openings for windows, especially mullion and triple frames, in frame and brick walls.

ROOF DESIGN.

From Z. R. N., Narvon, Pa.

I have a roof to erect over a shed 40° x 40°. The roof to be a lean to and to be self-supporting; that is, without any posts except in the outside walls. Can some reader give me a plan to erect above strong enough to carry a metal roof?

2. What will take stain off stone, caused by rain on chestnut sheathing running down over the wall?

3. Where an old building is chalky, is it right to paint over it without taking off the chalky substance? If not, please explain why.

PAINTING CONCRETE TENNIS COURT.

From A. P. H., Annapolis, Md.

I have made a concrete tennis court 130x50 ft. It is finished like a good pavement, but is too light in color. I would like to get it very dark green if possible. Can you tell me of any permanent material I could coat it with?

BEVELS OF HIPS.

From "Engineer," Edmonton, Alta.

Wanted, a diagram showing how the top bevels of a hip-rafter are obtained by the steel square, the hip to be cut to fit against the ridge.

BOOK.

From "T. L. W.," Phoenix, Ariz.

Which of Hodgson's Books would be of the greatest benefit to a young and inexperienced contractor just starting in business?

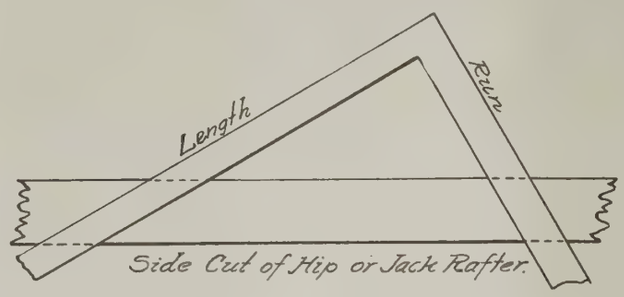
SAWDUST IN PLASTER.

From C. F. C., Buford, Colo.

I should like to have some information on the use of sawdust as a substitute for sand in plaster. How prepared, etc.

CARE OF CIRCULAR SAWS.

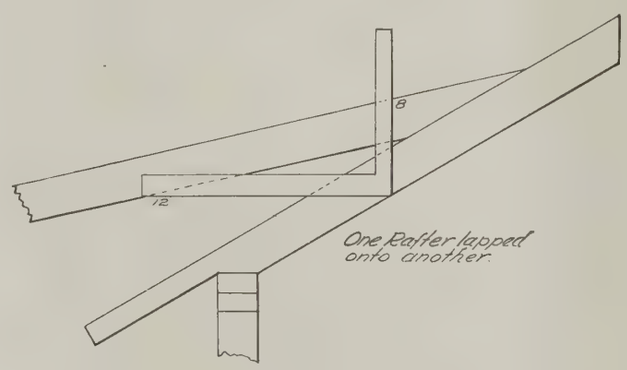
From C. F. C., Buford, Colo.



Where can I obtain a work on the care and management of circular saws?

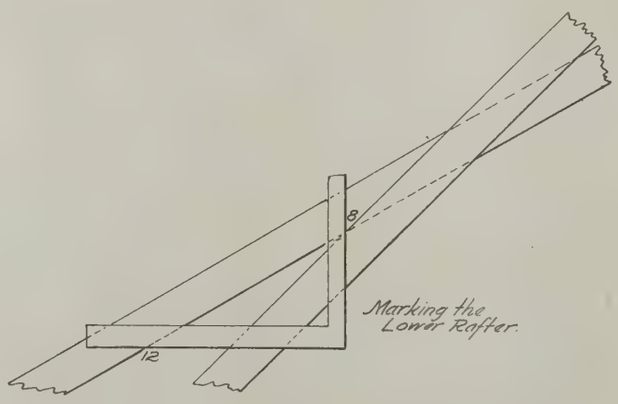
SOME RAFTER PROBLEMS

By JOHN UPTON



ORDINARY roof framing is not necessarily a difficult subject. Most of us can readily frame the rafters for a common roof of any required pitch, and generally a hip roof or a gambrel presents no great difficulties.

But sometimes when there are two roofs intersecting we get puzzled. I notice in one question department a man says he can

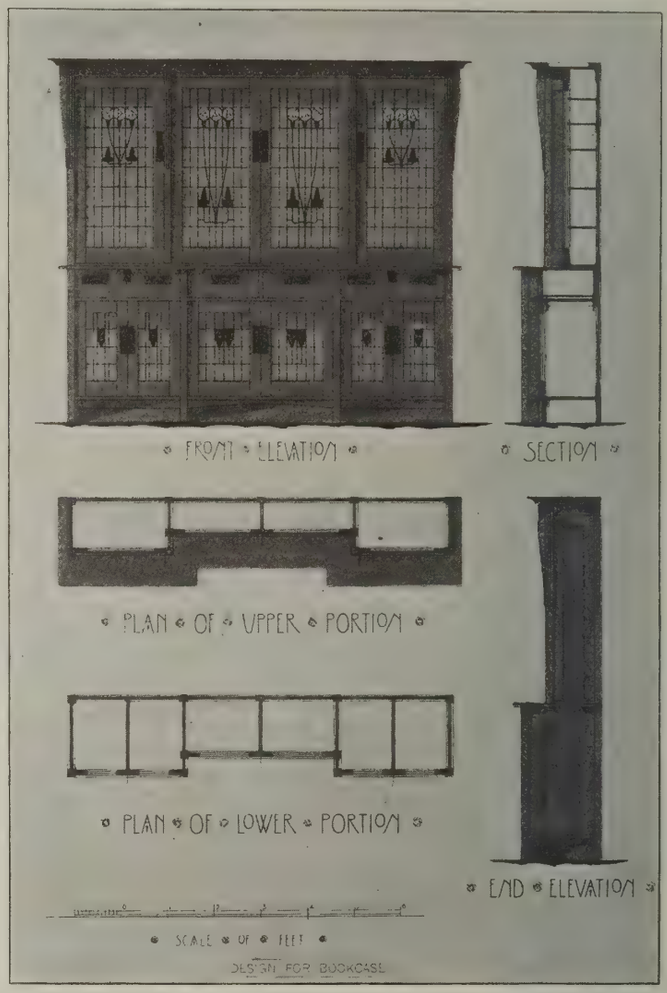


not get the joints of the half rafters to come right with the common rafters. Evidently this is not a pyramidal roof or there would be no common rafters. Perhaps there is no ridge in the center, or it may be joined onto another roof.

Supposing that the hips are at an angle of forty-five degrees with the plates. Then if they are to fit against the common rafters at the peak they should be cut with the same bevel on each side at the top. This would be the same bevel that they would be cut if

four hip rafters were to come together at the top, and is always something less than 45 degrees from the side of the rafter, for it would be this if they lay down flat, and their being raised up make it less. The more raise, the more slant to the cut. To cut them, use run and length of the rafter and cut on the length.

Another and perhaps better way in such a case as this, is to put the hip rafter up first, cutting them on one side only. Then cut the common rafters to match them.



Another puzzling case is where we want to cut the rafters for a lean-to roof which runs up onto a steeper roof; say a one-third pitch lapping onto a half pitch.

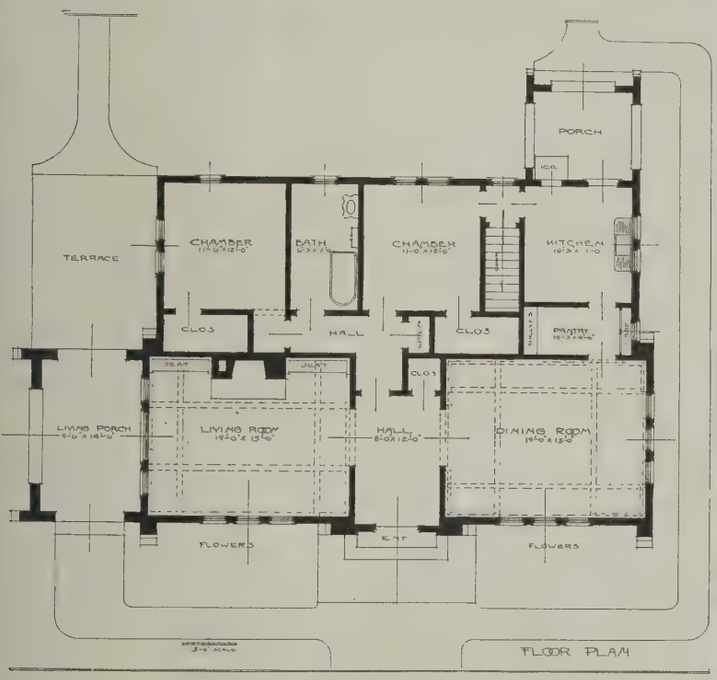
Lay the square on the rafter of the lower roof to find the plumb cut. From this lay off the pitch of the upper roof. In this case 45 degrees.

DESIGN FOR BOOKCASE

THE bookcase shown on the full page is published by request of several correspondents, and is intended to hold a large number of books.

This case is quite simple and easy to make, and is quite effective in appearance and not costly, the leaded glass being the most expensive, and the cost of this may be considerably lowered by simplifying the design. The brass hardware is plain and not at all costly. The plans and sections shown will given an idea as to

the construction, and the scale will enable the workman to get the proper dimensions. It may be made of hardwood and polished in the natural, or it may be made of softer woods.

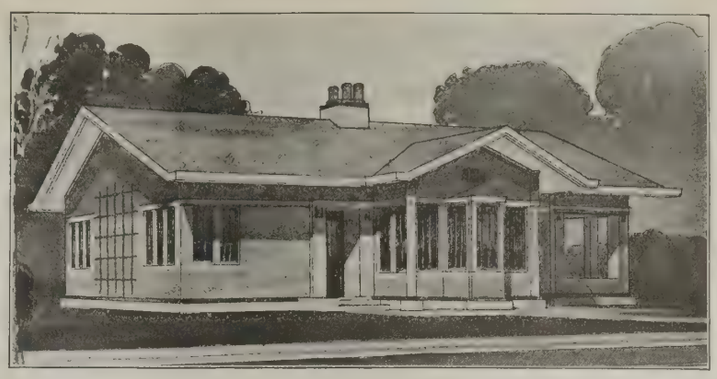


THREE CONCRETE BUNGALOWS

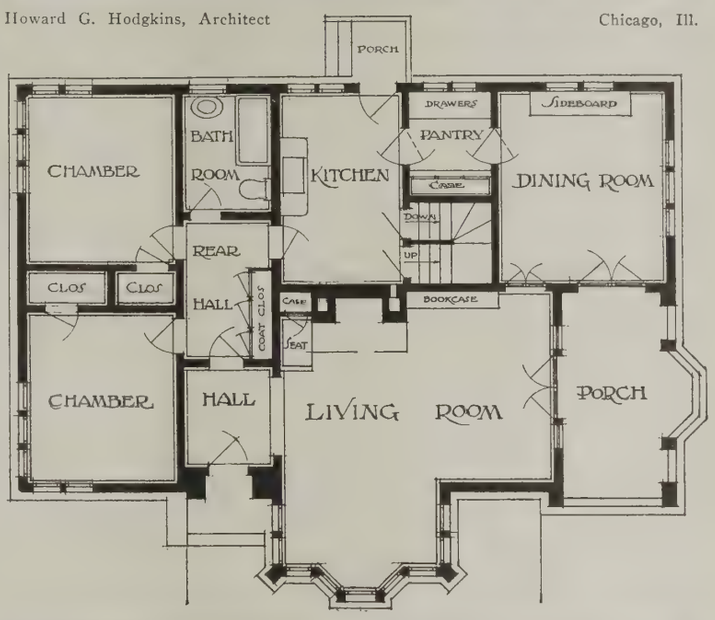
Through the courtesy of the Cement Products Exhibition Company, 72 West Adams street, Chicago, we show on this page three of the designs submitted in their recent competition.

The problem in this competition was to design a 5-room house

Frederick J. Smith, Architect — Indianapolis, Ind.



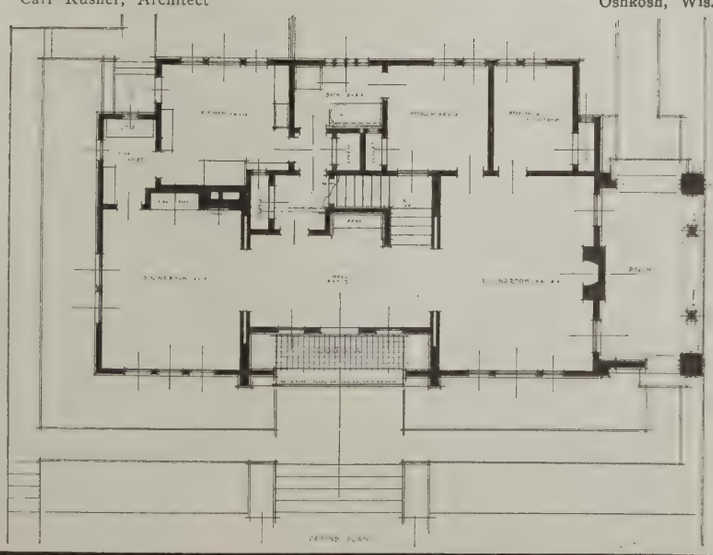
having fireproof walls, roof, etc., for $4,000, not including heating, lighting, plumbing and lighting fixtures.



The first design calls for monolithic concrete walls and floors, with red tile roof in front portion and gravel over rear. The interior trim to be stained cypress with birch doors.

The design, by Mr. Hodgkins, also calls for monolithic walls, with variations in color and texture of the interior surfaces to be obtained by using different grades of sand and gravel. The roof to have cement tiles.

Mr. Kusher, in the last design, calls for monolithic walls in the basement with block walls above grade, and tile roof, the support for which as well as the main floors being of concrete. Cypress will also be used for the trim and pergola.



Howard G. Hodgkins, Architect — Chicago, Ill.

Carl Kusher, Architect — Oshkosh, Wis.

NEW ACTIVITY IN LUMBER CIRCLES

There are many indications of "something doing" in the lumber business, and wood has still so many staunch friends among builders, even as against some of its meritorious rivals that we are glad to state that our investigations of the mysterious "yeast" evidently working in important lumber quarters have convinced us that great benefits are shortly to result to builders and investors, as well as a splendid stimulus to general lumber consumption.

The beginning of what seems to be a healthy upturn in the general lumber situation, occurred immediately after the elevation of E. G. Griggs of Tacoma to the presidency of the National Lumber Association last May, and has been developed thus far with energy, grasp and business foresight, said to be characteristic of the man.

It is apparently the intention of Mr. Griggs to make his administration signal from the start, and seemingly his idea is that if wood, as a whole, can be even measurably restored to its former high place in the general public esteem, he will have done more for the industry than had been expected of him.

Substitutes for wood have become so numerous, so varied, and in many cases so meritorious, that the general public inference has almost reached a point where uninformed people seem to think that "anything is better than wood."

Of course, no such broad condition exists. Wood is still plentiful, costs less than its substitutes, and deserves a revival, and Mr. Griggs has designated committees, including several of the biggest operators and broadest gauge men in the lumber industry to help put into effect his tremendous idea of systematic education of the entire public as to wood's real superiorities for countless uses in building and other industries.

We do not know if it has dawned on the big lumber men that, in our opinion at least, one of the most valuable results of such a line of publicity (if wisely thought out and skilfully handled) would be to correct a great many serious errors now in the public mind, as to lumber men, and lumber itself.

The lumber market, even to the smallest sales, has undoubtedly been almost as badly hurt by the public belief that "lumber barons" were abusing their alleged political power, as it has by the vigorous advertising of alternative materials. As a matter of fact the whole lumber industry would seem to have very little political power, judging by the doings of Congress, and from the fact that the Government's activities in lumber, under the Sherman law, have seemed to find themselves restricted to attacking selling groups, rather than any lumber manufacturers.

From our best information, it looks as though the working theory of the lumbermen's new national president was straight-out, up-to-date, commercial in character, instead of with political complications. If this is so, we think Mr. Grigg has hit the one and only cure for the unsatisfactory tendency of the industry, and if the method adopted shall be at once bold, conservative and circumspect, and the actual publicity handled with experienced skill and sure strokes such as have won such success for the Cypress and Red Gum campaigns (the only lumber advertising ever done up to now) we shall expect the lumber world to long remember the date when the president started out to unify it and set it on its feet again.

LONDON CARPENTER 400 YEARS AGO

WOLSTON WYN was a carpenter living in the reign of Henry VIII, and in the parish of St. Mary-at-Hill in the City of London, not far from London Bridge.

Mr. Wyn achieved no notoriety in his life. His name and work live today simply through the fact that the wages paid to him and the work for which they were given were set down in the accounts of the church-wardens of the parish in which he lived. These accounts, which are now deposited in the Guildhall Library, have been for the most part printed by the Early English Text Society.

We first hear of "Carpenter Wyn," as he is often called by the church-wardens, in 1520, when a tenant of the church expressed his willingness to pay such an amount for the "monyelles (mullions) of his bay windowe" as should be judged fair by Wyn. From the fact that the tenant (a Master Clayton) is stated in the records describing the arrangement to be "contented" with this plan, it is possible that Carpenter Wyn on this occasion occupied the position of arbitrator.

We next hear of Wyn in the same year as being employed to mend the paling round the churchyard.

In 1525 he was commissioned to ride on horseback to some wood to select the timber for the repair of the aisles of the church. The job took him two days, and was apparently in every way satisfactory.

Subsequently he assisted "to sett forth the sawyeres work and to helpe the tymbyer to the pyttes." The timber cost for "hewyng," beyond the price of its purchase, 2s., and the sawing into planks employed four men for many days. We do not know whence the wood was obtained, but the cost of making "sawe pyttes," on the spot was 1s. 4d., and the "caryagge in XII cartes of the said XI lodes timbyr, in plankes and bordes, from the wode to the watersyd, X. mylles," cost *li.* 12s.

At this time Mr. Wyn had married and had several children, for the fact of this work of choosing the wood necessitating his "beyng from his house, wife, and children" was considered in the amount paid to him. The payment for ordinary carpenters' work was commonly at the rate of 8d. a day, not at a rate per hour. Apparently, less than half a day, at 4d., was not considered. A boy would be paid at half the wages of a man. Sometimes, however, payment appears to have been made for the job and not by time. Carpenter Wyn had apparently another workman in his employ, and also a "boye."

An ordinary laborer would be paid considerably less than a carpenter. It must be borne in mind that the amount paid, whether for rent or wages, is not to be considered as representing the same money as today. In the Middle Ages the value represented by the penny, shilling, and pound was much greater than it is now. For this reason the sums mentioned in this little sketch are given only for the sake of comparison with each other.

In 1531 Master Wyn was employed to mend a stall and to supply staples for some shop windows, and in the same year a certain amount of money was due to him from the churchwardens. Here, however, at the time arose a difficulty, for the wardens, apparently being unable to pay the bill in full, had to have recourse to making part payment "in Redy monny" and giving, apparently as a pledge, or it may be to be retained entirely, six silver spoons, a salt holder, and a maser.

In 1535 Mr. Wyn had so far advanced in the consideration of the parish as to be made one of the churchwardens, an office in which he so well acquitted himself as to be again elected in the following year. It is not only from this fact that we know that he lived in the parish, but the records tell us that he lived in one of the best houses, one belonging to the church, for which he paid £3 6s. 8d. a year.

Whether Mr. Wyn had a taste for a flower and pleasure garden, or whether he desired to be independent in the purchase of his vegetables, we cannot now say, but we do know that he was sufficiently interested in gardening to induce him to pay a sum of 4s. a year for a piece of land for a garden in addition to that paid as rent for his house.

In 1539 occurred the death of his wife. What that meant to him and his children we cannot tell, the records merely contain the brief statement that the cost of her grave was 6s. 8d.

In 1553 he was still doing work for the church, much of which was entailed through the changes in the furniture occasioned by the Reformation.

In 1553 the King's Commissioners received various parcels of the valuables of the church. These valuables were handed over to those appointed to receive them "in the presence of Wolstone Win" and several other parishioners.

These Workmen Lose No Time

An Industrial Commission appointed by Congress was conducting certain investigations with reference to the operation of mills and factories in various parts of the country.

The investigators were in one mill in a southwestern state when the whistle blew for noon. The operatives put up their tools and vanished as if by magic.

"Do all workmen drop their tools the instant the whistle blows?" one of the commission asked.

"No, not all," the man who was acting as guide answered. "The more orderly have their tools all put away before that time." —Lippincott's.

RECENT COURT DECISIONS

A person may waive his right to a mechanic's lien.—Holm v. Chicago, M. & P. S. Ry. Co., 109 P. (Wash.) 799.

In determining liability on a builder's bond, the building contract must be considered, so far as relevant.—Harris v. Taylor, 129 S. W. (Mo.) 995.

The surety on a builder's bond is discharged from liability, where the owner does any act increasing the surety's risk without his assent.—Harris v. Taylor, 129 S. W. (Mo.) 995.

There is no privity between a subcontractor employed by a general building contractor and the owner, and the liability of the owner is only to the general contractor, who, on being paid, will become liable to the subcontractor.—McNulty v. Keyser Office Bldg. Co., 76 A. (Md.) 1113.

Where a contractor has completely abandoned his contract for the construction of a building, he has no implied authority thereafter to purchase material therefor, and his act in doing so is not binding upon the owner; it not appearing that the same was accepted and used in the building.—Lampert Lumber Co. v. Campfield, 127 N. W. (Minn.) 7.

Where building contract provisions for payments fairly construed afford an element of security inuring to the surety's benefit, any variation by the owner from such provisions which impair such security is a material alteration of the contract of suretyship, discharging the surety.—Harris v. Taylor, 129 S. W. (Mo.) 995.

Where a building contractor, required to provide all the materials and perform all the work called for under the direction of the architect without making any alterations except on a written order of the architect, employed a subcontractor under a contract containing similar provisions, the subcontractor could not recover for alleged extra work without evidence of a written order therefor or proof of a waiver of that requirement.—McNulty v. Keyser Office Bldg. Co., 76 A. (Md.) 1113.

Where a written agreement between the owners and principal contractor fixed the time limit within which the work is to be completed and after which damages shall be allowed if the work is not completed, it is within the power of the parties to change said time limit by oral agreement, afterward made, extending the time, and the courts will respect such change, made in good faith, and refuse damages suffered prior to the date fixed by the change.—Campbell v. Kimball, 127 N. W. (Neb.) 142.

A stipulation in a building contract that, on the contractor being delayed by the default of the owner or the architect or of any other contractor employed by the owner, the time fixed for the completion of the work shall be extended for a time equivalent to the period lost by such default, has no reference to extra work, and does not confer on the architect implied authority to bind the owner by his direction to the subcontractor to do work claimed by the subcontractor not to be within the contract.—McNulty v. Keyser Office Bldg. Co., 76 A. (Md.) 1113.

A subcontractor was informed by his contract with the general contractor that the latter was a general contractor, and that a third person was the architect, supervising the performance of both contracts. He was told by a representative of the general contractor that he could not allow him for certain work, because, under his contract with the owner, he could get no allowance therefor without a written order from the architect. The subcontractor performed the work without any written order from the architect. Held not to show an estoppel by holding out the architect as having further authority than that limited by the contract, and the subcontractor could not recover from the owner for the work on the theory that the latter had held out the architect as possessing authority to direct the work.—McNulty v. Keyser Office Bldg. Co., 76 A. (Md.) 1113.

PATENTS.

The following list of recent patents and trademarks relating to building interests is especially reported for THE NATIONAL BUILDER by Wm. G. Henderson, solicitor of American and foreign patents and trademarks, Norris building, 501 F street, Washington, D. C. A copy of any of the United States patents will be furnished by him for 25 cents.

996,845. Metallic window-frame, etc. Alexander Fromhold, Rutherford, N. J., assignor to S. H. Pomeroy Company, New York, N. Y.

997,059. Machine for cutting window-frame pockets. Warren B. Harris, Millbury, Mass.

997,433. Hinge for doors. Abraham L. Adler, New York, N. Y.

997,596. Brick or block and wall construction. Francis J. Arbogast, assignor to Standard Glass Block Co., Frankfort, Ky.

997,435. Column or post. William J. J. Bowman, Trenton, N. J., assignor to the J. L. Mott Iron Works.

997,662. Weather-strip. Andrew F. Ewing, Asbury Park, N. J.

997,449. Hinge. William A. Henn and M. D. Helfrich, Evansville, Ind.

997,876. Sash-lock. Warren B. Weaver, Lakeland, Fla.

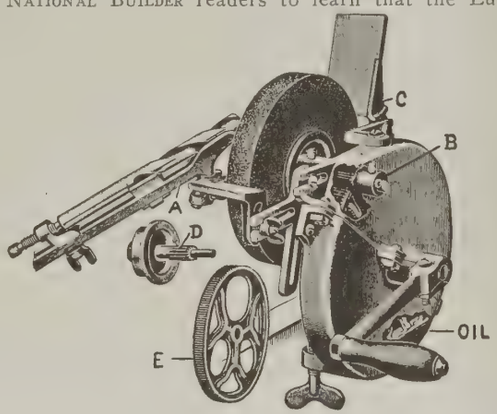
998,293. Building partition. Louis F. Jackson, assignor to Davis-Jackson Supply Co., Denver, Colo.

998,346. Weather-strip. Levi Knott, Altoona, Pa.

998,584. Door-check. Jos. M. Martin, assignor one-half to H. Burkhart, Bay City, Texas.

999,030. Concrete building construction. Frank B. Hodge, Revere, Mass.

999,051. Floor-scraper. Jno. D. McCurdy, Duluth, Minn.



999,126. Collapsible scaffolding and like structures. G. Sisterman, Cologne, Germany.

LUTHER GRINDERS.

Advance and expansion being the most visible effect of the business-like manufacture of articles of merit it will no doubt be gratifying to NATIONAL BUILDER readers to learn that the Luther Grinder

Manufacturing Co., 1708 Madison St., Milwaukee, Wis., find it necessary to occupy more space, although their factory has over an acre of floor space. They have accordingly taken an entire floor in the Stroh building, one of Milwaukee's newest office buildings, for their general offices, printing plant, etc.

Mr. Luther started to manufacture grinding machines sixteen years ago, at that time the machine in general use was the sand grindstone, which largely through his efforts has been almost entirely replaced by wheels of faster cutting materials. For many years carborundum was used, but recently, after extensive tests lasting a long time, a new substance, "Dimogrit," has been adopted. "Dimogrit" seems to be a perfect material for use with steel tools, where the perfect temper must be kept on the thin edges. It has taken years of persistent work to convince mechanics that a large part of the time spent over a grindstone was wasted. Now the grindstone is practically replaced by much smaller machines which will do the same work in one-tenth of the time.

The policy of the Luther Grinder Mfg. Co. has always been one of extreme liberality toward those unacquainted with the merits of their machines. Their booklets are full of accurate information and can be had for the asking.

PORTABLE SAW RIGS.

During the last forty years, there has been a great change in building, not only in design, construction and detail, but also the materials, methods of erecting and in the personal work of the various trades. At one time practically all the carpenter work was got out by hand, from hewing the sills to the interior finish. The erection of a building of any pretention was a long job, sometimes lasting through several summers. Much of the work was done in the shop in the winter, such as getting out frames, sash, trim, etc., storing it up until the building was ready for it. Very little outside risk was done in the winter, the frame being allowed to "season" and "settle."

Now, keeping up with progress in other lines of business, the progressive builder must prosecute his work actively at all seasons of the year. Cold weather is no longer an excuse for delay. He must have his buildings in shape to keep going until completion. The work on frames, sash, trim and millwork, formerly done in spare time in the shop, is now contracted for at a mill, which is probably getting out a dozen or more jobs at the same time. To a certain extent, this eliminates his "shop," except as a storehouse for left-over material, which, useless for new work, can only be used upon the occasional repair job.

Progress with the mill work has also been followed by new and better hand tools, so that the mechanic is capable of more work than formerly. In fact, it is claimed that a mechanic now does in eight hours what formerly took ten to do.

On the job, we find a number of labor saving devices. Frequently on large work, a steam shovel does the excavating, and a power elevator raises the brick, mortar, and other materials. Every machine installed means less manual labor, as well as a saving in time. The saving in these items constitute actual profit and are often depended upon to secure the contract, not only by the actual saving, but by the prestige the contractor enjoys through using up-to-date methods and equipment.

For saving time, labor and material, it is probable that no one item has more possibilities than the Portable Saw Rig. This machine is made in a variety of forms differing somewhat in construction and variety of work, but in general it consists of a substantial bench, mounted on skids for easy conveyance from place to place or from job to job. The table is equipped with rip and cross saws, boring, sanding and moulding devices as a rule, and various other attachments for doing special work. Power for its operation can be from a self-contained gasoline or electric motor, or when in a shop, from the regular shop shafting if desired.

The variety of work which can be performed on a rig of this character is generally limited only by the ingenuity of the operator. For working dimension material it practically takes the place of a well equipped mill. Some styles allow two or more men to work independently on the machine at one time, doing such work as sawing, boring, grinding, etc. For repair work it is especially useful, as one or two pieces can be made up in a hurry, the change on the machine occupying a very short time.

As generally constructed, the machine is self-contained, furnishes its own power, and can be readily moved from the shop to the job, from floor to floor, room to room, or placed in front of a door or window to accmmodate material in long lengths, or take advantage of the light or other conditions. This portability keeps the entire work on the job and allows a vast amount of work to be done without loss of time or transportation to and from the mill or shop.

Prominent among the manufacturers of woodworking machinery, the Oshkosh Manufacturing Co., formerly the Oshkosh Logging Tool Co., of 414 S. Main street, Oshkosh, Wis., deserves special mention. Since 1843, they have been engaged in the manufacture of tools, appliances and machinery for lumber and wood workers, and now occupy the whole of the building shown herewith. Their experience would indicate ability to design a saw rig to meet present conditions, and their announcement that they considered their Portable Saw Rig the best in the market for the contractor is entitled to serious consideration. On the Eveready Saw Rigs is found every attachment necessary for the most exacting work, the machine being equipped for cross and rip and jig sawing, boring, sanding, mitering, with heads for dadoing and jointing, and an emery wheel to keep the various blades and other tools in condition. The frame of the machine is hard wood, well bolted together and the makers have so much confidence in the outfit that they make their guarantee "for life."

Contractors considering the purchase of a Portable Saw Rig should get the information, prices, etc., relative to the Eveready. The makers court the fullest investigation, both for themselves and their product. Knowing that every reader of the NATIONAL BUILDER is interested, they are offering to send any desired information free, and their terms of sale include, "If Not Satisfactory, Return at Our Expense."

¶ That's what one Carpenter said when writing about his experience with Simonds Hand Saws.

¶ It would be entirely too broad a claim to say that none of them ever did come back, but we believe that dealers have to give "money back" on fewer Simonds Saws than any other brand of Hand Saws.

¶ Here's what one dealer in a large city in Pennsylvania writes: "The Saws I return you by express are the only ones to my knowledge returned for exchange in all the years I have bought your line. We have less exchanges on Simonds Saws than on any other brand and sell twice as many of them."

¶ A Carpenter in Cairo, N. Y., writes: "Five years ago I bought two Simonds Hand Saws, one Rip and one Cut-off. They are certainly the nicest running saws I have ever used. The Dealer said if they were not better than any other make I ever used to bring them back. I never took them back."

¶ Ask your Hardware Dealer for Simonds Hand Saws or write us about the kind of a Saw you are wanting.

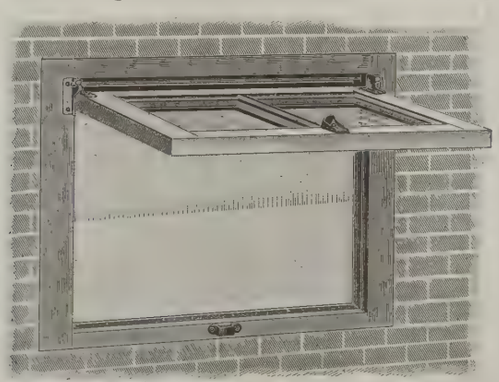
THE JOHNS-MANVILLE BUILDING.

Very few concerns in this country do such a volume of business as to require a twelve-story building for their sole use. We are pleased to note that the H. W. Johns-Manville Co. find such a building necessary, and have so far completed it that they expect to occupy their new offices about May 1st.

The exterior of the building will be limestone for the three lower stories, with gray-brown Roman brick and terra cotta above, ornamented with panels of various colored marbles in terra cotta frames. The interior is planned to allow the different departments to occupy separate floors with the executive office on the eleventh floor and the entire twelfth floor for an exhibit and sample room.



An unusual feature connected with this building will be the fact that the tenant manufactures and will furnish a considerable part of the equipment of the structure. Among the various materials which the H. W. Johns-Manville Co. will install will be the following: J-M Asbestos Roofing, J-M Asbestos Plaster, J-M Linolith System of Lighting, J-M Conduit for wiring, Flushometers, J-M Sanitor Seats, electrical accessories, waterproofing, Keystone hair insulator, J-M asbestos wood, fire extinguishers, J-M Asbesto-Sponge Felted and J-M Asbestocel Pipe Covering, etc.

The name of "H. W. Johns-Manville Co." and "Asbestos and Magnesia" have so long been synonymous, that many will be surprised to learn that this company also manufactures a very large line of electrical goods, plumbers' supplies, building materials, automobile supplies, cold storage insulation materials, railroad supplies, etc.

HARDWARE SPECIALTIES.

Specialties are found in every line of work. In the builders' hardware, there is almost daily brought out some new device, tool or machine, for doing more work, better or faster work, or improving the appearance and usefulness of work now in place.

Among the special places which have not received the attention they deserve, we find the basement window. Too often this is hung on common butts or strap hinges, entirely inadequate and unsatisfactory. It is a pleasure to mention in this connection, Diehl's steel basement window hinge. The makers claim these to be the only self-

supporting or bracket hinges on the market. The sash is held open without the use of ceiling hooks, bolts or other contrivances. By raising the sash up to a horizontal position it is possible to slide it backward and it stays locked in that position until the reverse motion allows it to close. Should it be necessary to remove the entire sash, it is easily done without removing a screw.

This hinge is made in different styles, all, however, having the above good qualities. Besides this hinge, the Diehl Novelty Co., Sheboygan, Wis., make a large number of hardware novelties, such as screen door hinges and catches, sash locks, storm sash hangers, etc. A contractor having their catalogue handy is never at a loss to find a specialty adapted to his particular use.

DISSTON'S INTEREST IN THE CARPENTERS.

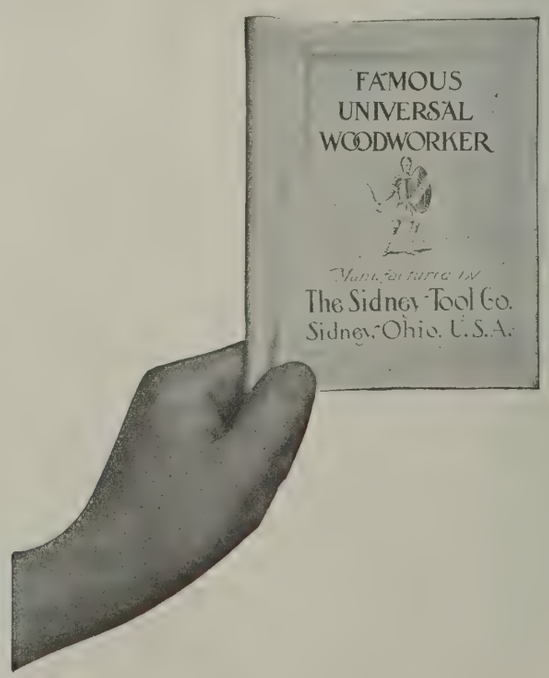
When our wise forefathers established the United States Patent Office, the idea foremost in their thoughts was to protect the originator of a new idea. The question was of the form and arrangement rather than the quality of the article. In granting protection it was left to the patentee to establish the quality independent of quantity. In other words, the patent did not and could not guarantee the quality of the product.

At this late day we cannot tell what the originators of the patent laws would think of conditions at present. It is a fact that many inventors do not now patent their ideas, but depend more on the quality of their product to protect them from infringement. And it seems to be true that the highest quality of product is found in goods on which there is no basic patent. This applies particularly to tools and appliances used in the building trades. The conscientious manufacturer knows that his NAME on an article of merit is far more potent than PAT. No. 999,999, for it means QUALITY, REPUTATION, SINCERITY.

With modern methods of advertising, the market for tools and other building appliances has broadened enormously. Certain trade names become a by-word for quality, and the new manufacturer promptly realizes that the guarantee of the established factory creates a demand which cannot be met with a mere lower price.

It is to such companies as Henry Disston & Sons, Philadelphia, that the newer or smaller concern compares his goods and prices. Few who have an article of merit have the temerity to say their goods are BETTER than the older products, and at equal prices the new goods are at a disadvantage, for no intelligent mechanic will accept goods whose quality has not been proven by years of usage when he can get the articles of established reputation.

The question naturally arises: "How is this condition kept up, and how do the firms like Disston & Sons keep their trade in the face of many competitors?"



In the first place, the quality must not only be maintained, but raised as fast as improved methods of manufacture and materials can be proven to be of value. The most careful manufacture and inspection will sometimes fail to discover a hidden flaw, and a broad and liberal guarantee must be exercised immediately on the discovery of any complaint. Not all complaints are justified, perhaps, but it gives the manufacturer a chance to see what fault is found.

With the cheaper makes, the "just-as-good-at-half-the-price," this form of complaint cannot be entered, for the maker has no prestige to maintain and only too frequently merely makes the goods **to sell** in **competition,** and is unapproachable either through dealer, wholesaler or direct. The company with a reputation welcomes a complaint; the others avoid them. The established concern follows his goods to the workshop and the job, and advertises the fact that it stands back of the goods and can be easily reached through the dealer or direct. These concerns aid the workman by personal instruction, by circulars, by demonstrations and exhibits. The carpenter today **knows** that the name "Henry Disston & Sons" is a mark of quality intended for him, and a guarantee that the saw, or file, or other tool is what it should be.

FAMOUS UNIVERSAL WOODWORK CATALOGUE.

A very complete catalogue of the "Famous" woodworking tools is now ready for distribution. Most of our readers are acquainted with this class of machinery through the advertisement of the Sidney Tool Company, but the new work contains a great deal of information of additional interest.

The catalogue is of a handy pocket size which covers practically every feature connected with woodworkers. The explanation of the

economic conditions which made such machines possible and the construction of the machines, resulting in the economy of labor, time and floor space, makes interesting reading.

Those of our readers who are not already on the mailing lists of the Sidney Tool Company, Sidney, Ohio, should send their names in and secure this valuable book.

Perfect Results are Easily Obtained by Using Schlueter Rapid Floor Surfacer

This machine is built on the only correct principle. It is guaranteed to be **The Best** machine with which to produce an even, smooth service on any kind of large or small wood floor, old or new, hard or soft, and in all buildings: Residences, Stores, Factories, Bowling Alleys, Roller Skating Rinks, Reception and Dance Halls, Etc.

The **Schlueter** will remove all joints or warped edges, and oil, wax, lime stains, or the "muck" from skate wheels, in a most satisfactory manner.

UNION LOCK SETS.

A well-to-do farmer walked into the Rehm Hardware Company's place of business a few days ago and instead of buying the cheapest locks and builder's hardware he could get for a new residence he was erecting, placed an order for the very latest designs and best finishes, which amounted to about three times what the average farmer would have placed in his building four or five years ago. This incident goes to show that many property owners outside of the large cities are really putting better materials into their homes and buildings than their city brothers. It is a well known fact that fine builder's hardware with good interior finish makes a combination that is both pleasing and substantial. It adds far more to the value of the building in proportion to the actual cost than some people would suppose. The up-to-date contractor and builder is today in a position to select the latest designs and finishes and get them at very reasonable prices.

One of the few big concerns publishing a well illustrated catalogue on builder's hardware is the Rehm Hardware Company, 1503 Blue Island avenue, Chicago. About the first thing brought to the attention of the reader in the Rehm catalogue is a union lock set, shown here. It has become decidedly popular with architects, contractors, builders and property owners, and is described as follows:

The wrought steel working parts of the lock set are machine made and are exactly uniform as to size; they will not break, and the construction is such that they cannot fall apart or get out of place; they are carefully fitted, insuring a perfect action and great durability. They are on the inside of the door, so that it is impossible to get at them from the outside, and there is nothing to bind or get out of order or jar out of place and interfere with the proper working of the lock set. The two parts of the lock set telescope together and are quickly applied and securely attached by the two machine screws for the escutcheons and the two wood screws for the face of the lock.

They leave the factory fitted, adjusted, inspected and complete, ready to put on the door. They are adjustable for doors from 1⅝ to 2¾ inches thick and can be furnished to order for other thicknesses.

The appearance of the Union Lock Set is that of the knob and escutcheon used with the familiar type of cylinder locks, except that there are no screws on the outside of the door. The cylinder is in its usual and most convenient place, where people are accustomed to look for it.

Both bolts are operated from the outside by the key. The dead bolt is operated from the inside by the thumb knob. The latch bolt is operated from both sides by the knobs. The outside knob is set by the knob stop on the inside of the door.

Union Lock Sets are easily applied by using the template as packed with each set. Simply bore four holes in the door with a ⅞-inch auger bit and make a few cuts with the chisel. Only a small part of the wood is cut away, consequently the door is not weakened.

It will be seen from the illustration shown here that the placing of this lock on the door is a very simple piece of work. The idea of not being obliged to cut out a large part of the door for a lock set of this kind is an exclusive feature of the Union Lock Set.

The Union Lock Sets not only give a door a very substantial appearance, but on account of the design and the fine finishes in which they are made, add greatly to the beauty of any door.

Many other late designs in fine builder's hardware are to be found in the Rehm Hardware Company's catalogue No. 5. For those who are looking for special bargains, when writing for the catalogue, it would be well to ask to receive copies of the Rehm Hardware Company's Bulletin. This Bulletin is sent out on request to anyone located outside of Cook County. It shows a fine line of builder's hardware, sash weights, chain bolts, cupboard turns, sash locks, door handles, etc., at some very interesting net prices. The fact that these prices are low does not detract from their quality as the Rehm Hardware Company have always been known for their high-class line of goods. They buy and carry an unusually large stock and are, therefore, able to give the readers of THE NATIONAL BUILDER the best in builder's hardware at the lowest prices and this, coupled with prompt shipments and fair dealings, has won and held for them a great many customers among the best class of builders.

Asbestos "Century" Shingle Roof—Residence of George Jacka, Calumet, Michigan; Architect, Paul Humphrey MacNeil, Calumet, Michigan; Contractor, Edward Ulseth, Calumet, Michigan.

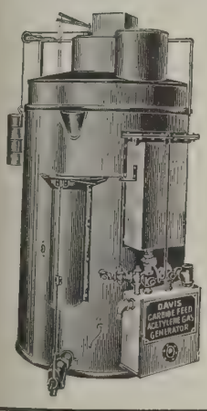
Asbestos "Century" Shingles

"The Roof that Outlives the Building"

EVERY cent your client puts into an Asbestos "Century" Shingle roof buys wear and service—protection against fire and weather—insurance against bills for repairs and painting.

You can't say as much for any other roofing on the market.

Asbestos "Century" Shingles are practical, lightweight shingles of reinforced concrete — made of hydraulic cement reinforced with interlacing asbestos fibers.



They are absolutely indestructible by weather and time. Fire cannot burn them, melt, chip or flake them. Their first cost is about what the property owner would expect to pay for a first-class roofing—and there's the end of the expense.

No repairs—no painting.

You can get Asbestos "Century" Shingles in three colors—Newport gray (silver gray), Slate (blue black) and Indian red—in numerous shapes and sizes. Write for booklet "K & M 1911."

Strength, Beauty and Service

The three necessary elements required in a material of QUALITY

For **ROOFING** and **SIDING**

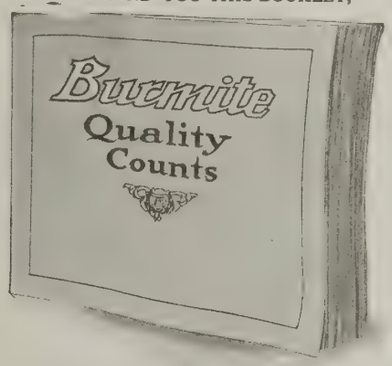
Buildings of any kind of construction—*be they new or old,* are combined to the greatest extent in

Ready-To-Lay

Burmite

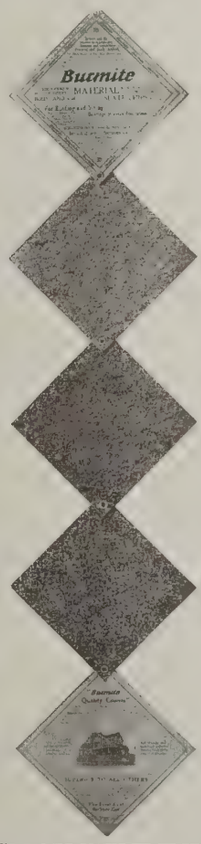
(REG. U. S. PAT. OFF.)

A FLEXIBLE-CEMENT-BURLAP INSERTED MATERIAL



Recognized and acknowledged to be the most **Durable, Practical** and **Inexpensive** for use as a Roofing and Siding. **GOOD Shingles are Out of the Question.** Metal and Slate are too expensive to use on the average building, and for these reasons the time has come when you must look for something else to cover your roofs with besides shingles.

"BURMITE" lasts longer than shingles—*costs less, lays smoother, looks nicer and requires no paint to preserve it. Can be laid over old shingles or tin;* is odorless, will not "run" on steep roofs; and on account of its unusual flexibility is especially well adapted to **flat or uneven surfaces.** **"BURMITE"** *positively makes good* and is **Guaranteed for 10 years without Coating or Painting.** ¶ We couldn't afford to make these statements were they not facts, any more than you could afford to recommend or use an inferior article for a customer of yours. We know that **"BURMITE"** is an **honest value for discriminating people,** and invite your closest and most critical investigation of our claims and severest test of our Samples. Made to meet **Extreme Weather Conditions** in two separate and distinct surfaces, i. e.,



BIRD-SAND and "*Twolayr*" Slate Chips

Cheap roofing is expensive at any price—must be painted at least three times in the course of from seven to ten years. **"BURMITE"** requires no paint—hence is the most economical to buy. It can be used in any climate—does not dry out—remains flexible always.

LET US SEND YOU THIS BOOKLET,

illustrated with buildings beautifully printed in colors showing effect of **"BURMITE"** applied as a Roofing and Siding on **Residences, Summer Homes, Cottages, Bungalows, Garages, Barns, etc.,** and **THIS SET OF SAMPLES,** so that you can compare roofings you've handled—apply and then let us explain our **"BURMITE"** with other your own tests in your own way **Special Service to Build-**ers which will help you to ntroduce it in your locality.

"Stoddard" SLATE-GREEN *"Burmite"*

IS UNEQUALLED FOR ATTRACTIVENESS IN COLOR AND LASTING QUALITIES

SLATE-RED *"Burmite"*

Used with or without the Green, is another winner for the Architect, Contractor, Builder or Dealer, as a Roofing and Siding.

BIRD-SAND *"Burmite"*

For Residences, Business and Factory Buildings, Elevators, Warehouses, Barns, etc. It is easier to lay, more handy and superior to other roofings.

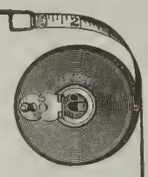
CONTRACTOR'S TRANSITS AND LEVELS.



We are advised by the David White Co., 421 E. Water street, Milwaukee, Wis., that they have several new models of instruments for contractors' and architects' use and are making the prices and terms such that no contractor needs to be without these necessary instruments of precision.

A good instrument saves its cost on even a small job, by doing the work at the right time, and there is the added satisfaction of knowing that the work is absolutely correct. A building out of square or level, or not correctly laid out, often means costly delay and trouble, and it can be easily avoided. Levelling with a straightedge and carpenters' level permits too many errors, besides taking too much time, and the time of several men, while with a WHITE'S IMPROVED LEVEL OR TRANSIT, the work is done accurately and quickly and with every appearance of good workmanship.

The David White Company are planning to place one of their instruments with every contractor in the United States. If you are in need of an instrument write to them, get their full particulars and prices. We understand that they have special terms for readers of the NATIONAL BUILDER.

Topp's Framing Tool

A PERFECT TOOL, AND THE ONLY TOOL FOR THE PURPOSE EVER INVENTED

Saves from 3 to 24 hours in laying out a single roof. Saves time for the skilled mechanic, and enables the ordinary workman to frame the most difficult roof with absolute certainty.

IT DOES ALL THIS

It is accurate, thus preventing all mistakes.
It gives angles for any pitch.
It gives lengths for any rafters.
It gives cuts for principals, jacks, hips, valleys and cripples.

PRICE, $1.75

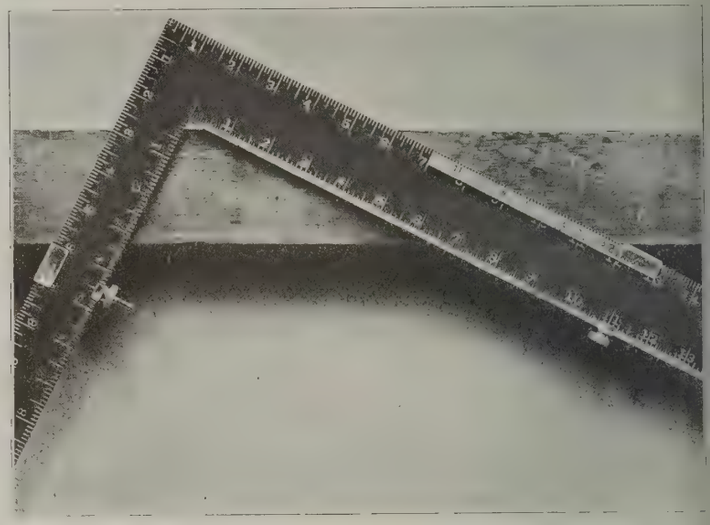
G. A. TOPP & CO., Indianapolis, Ind. See tool at Your Hardware Dealer's.

The Ackermann Floor Scraper

saves its cost on the first job. With the Ackermann patent sharpener (free with the machine) any man can sharpen knives. Send for Catalog and our FREE TRIAL offer.

The Monarch Concrete Mixer

produces 4 to 6 cubic yards of concrete per hour with 2 men to do all the work. Saves its cost in less than a season's work. Send for catalog of complete line of concrete machinery.



Monarch Mfg. Co., 259 Shepard Building Grand Rapids, Mich.

THE NEW PARKHILL PITCH GAUGE FOR ROOF FRAMING.

Probably no one tool or instrument is more useful to the carpenter or builder than the steel square. By its use the most difficult problems in framing are easily and accurately solved. The modern steel square is for this reason found in every tool kit, and its owner usually understands the principals on which it should be used in framing or laying out his work.

Complete as the square may be, there are certain manipulations necessary in laying out even the plainest work. To lay out a common rafter with a rise of 6 in. to the foot for instance, we know it is only necessary to use 12 in. on the blade and 6 in. on the tongue and the line across these marks will give us the length per foot to run. This is shown in the illustration. But it is a more difficult matter to hold the square exactly on these marks while we mark off for one foot, and this is one of the chief limitations of the steel square.

For many years Mr. John Parkhill of Rochester, Minnesota, has studied along the line of greater accuracy and rapidity of the work

with the steel square, and the results of his efforts are embodied in his New Pitch Gauge patented last December.

As will be seen by the illustrations it consists of two parts which may be clamped to the square at any point on either the tongue or blade, thereby forming a perfect "fence" for laying out any class of work.

It will be noted that one of these pieces—the gauge proper—has a long extension arm or strip which is graduated with a special series of numbered marks. These marks are the most essential feature of the tool, and serve to eliminate all calculations thus enabling any one to quickly mark with mathematical accuracy for any roof pitch, all rafter lengths, cuts, bevels, and backing, also sheathing, facia, plancher, hopper bevels, etc.

While it might seem that this is too much for such a simple instrument to do, the patentee and manufacturer, Mr. John Parkhill, Rochester, Minnesota, will be glad to explain its use in more detail. The terms on which it is sold permits its return within thirty days, but we believe the gauge is so useful that there will be repeat orders rather than a request for a refund.

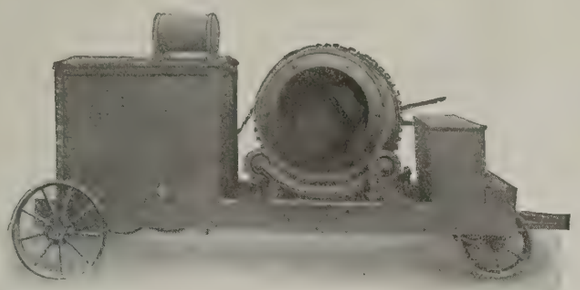
THE ALDINE FIREPLACE.

While there has been a steady change in style and fitments in the modern house, one item still remains which no one wishes to, or can, dispense with. The fireplace with its cheery welcome is the constant reminder of hospitality.

During all the years there has been a constant effort to improve along all lines. We now have large sheets of plate glass where formerly we had only small frames of very inferior glass. In steam and hot water heating we have advanced from crude systems to vacuum systems and thermostatic control with corresponding fuel economy and ease of operation.

In fireplace design, some of the manufacturers have shown equal genius in keeping up with the advance in ideas, while others are still making and using the patterns of forty to fifty years ago. Probably no concern has shown more originality in design than the Rathbone Fireplace Manufacturing Company, 6208 Clyde Park avenue, Grand Rapids, Michigan. In the Aldine, the continuation of improvements can be understood from the numerous patents which have been allowed, the last dated April, 1908.

As at present constructed, the Aldine Fireplace can use any form of fuel, including natural and artificial gas, with the best heating results at the lowest fuel cost. The highest development is shown in the sanitary, ventilating, and heat distributing principles. While with other fireplaces it is necessary to replenish with fuel every few hours, in the Aldine a coal fire will keep all night without attention, giving off a good heat all the time. The construction is such that a constant circulation of air is maintained in the room, thereby warming the otherwise cold corners.



The Aldine can readily be installed in old houses, to take the place of otherwise unsatisfactory heating apparatus, and, as it required no special chimney or mantel construction, can be placed in any room. The use of an Aldine for six weeks in the fall before a furnace is actually needed and in the spring during the cold days and evenings, will warm comfortably two or three rooms, which otherwise would be chilly.

The Rathbone Fireplace Manufacturing Company have some very interesting reading matter which every reader of THE NATIONAL BUILDER should secure concerning the manufacture and advantages of the Aldine Fireplace.

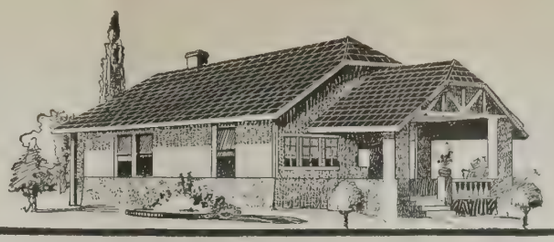
"The Largest Line of Concrete Machinery in the World"

Northwestern Contractors' Power Batch Mixer



This machine combines all of the features which every contractor or concrete worker desires in a mixer. It has such a low intake that the material can be shoveled in from the ground or a small platform built and the material dumped right into the mixer with wheelbarrows. It has a high discharge and will empty into a wheelbarrow or into the forms. It is light and portable and can be readily moved from place to place. It has automatic watering tank and can be adjusted to discharge any given amount of water each batch. It will hold a full sack of cement with practically any mixture. It can be equipped with a power, stationary loader or low platform. We guarantee that this mixer will cost you $100 to $200 less than any standard mixing machine of equal capacity on the market.

Don't Fail to Send for Our Big Catalog

We manufacture everything in the concrete machinery line, including mixers of every style, size and description and we can furnish everything that you might need in the concrete line. Regardless of whether you are in the market or not you should have a copy of this catalog. Please state what you are interested in as we issue four (4) special catalogs. We are the largest manufacturers in the world and prepared to serve you with machines extremely low in price, simple in design and speedy in operation.

The Roof That Never Wears Out

¶ The roof that architects, contractors, builders and best informed home-owners recommend—is a roof of ***solid rock***—slate.

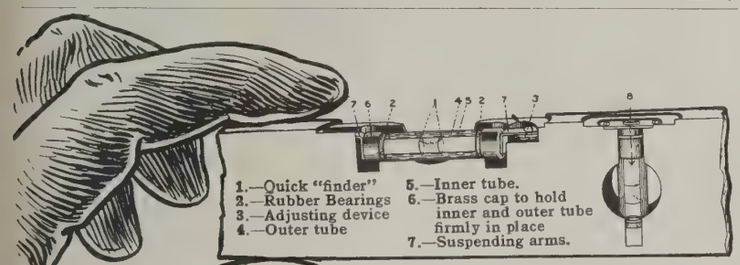
¶ And when you consider its ***value,*** its enduring, imperishable qualities, isn't it only reasonable that you should choose such a roof? Isn't it only fair to yourself or to those who look to you for advice in such matters, to recommend

Sea Green or Purple Roofing Slate

as the one roofing material that ***never*** wears out?

¶ Sea Green or Purple Slate is the only roofing that absolutely resists the action of air, water, sun, fire, or lightning. It is never affected by rot, or rust; it will not crack, warp, blister or decay; it wears many times better or longer than any other roofing and never needs paint or repairing.

Send for Our Free Booklet "Roofs"



¶ Get the specific, unbiased facts—the opinions and experiences of home-builders, and roofing experts ***now.*** Then judge the value of Sea Green or Purple Roofing Slate for yourself.

¶ Write a post card and tell us to send you a copy of "Roofs" today, and settle all roofing troubles forever.

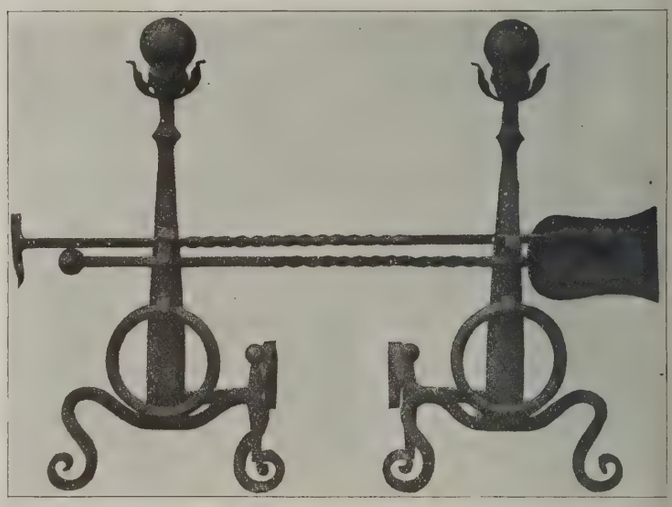
NEW STYLES IN MANTELS.



Home building, as a rule, occurs only once in a man's life. The thought expended on location, price, plan and construction are all more or less dependent upon fixed customs. To a certain extent, the design, the personal appearance, is a man's own individuality. Upon no one part is this personality reflected more than in the selection of

the mantel. While the selection made should harmonize with the adjoining woodwork, the mantel should be correct itself, in architectural design, as well as in construction.

Among the newer ideas in mantel construction for homes of moderate cost, Faience Tile has many features of excellence—simplicity of design, soft, pleasing blends of colors and texture, a material not affected by heat or moisture, a style which is particularly suitable for rooms finished in Mission or Craftsman styles, although its use in the older styles of finish is in perfectly good taste.

The accompanying illustration shows a pleasing design in Rock-

wood Faience, which is made in almost every conceivable shade, as well as with decorated panels from stock or special designs.

The complete list of mantels and accessories made by Moormann & Otten, 611-613 Main street, Cincinnati, Ohio, is so large that two catalogues are necessary to fully describe them. Home builders will find so much interest in them that they are urged to send for these catalogues before placing their orders for this part of the home.

CONCRETE AND MORTAR MIXERS.

We learn that the Lansing Wheelbarrow Co., 14 Grand street, Lansing, Mich., has purchased the assets of the Advance Concrete Mixer Co., of Jackson, Mich., and will continue the manufacture of that line of Concrete and Mortar Mixers in connection with their former line of trucks, wheelbarrows, automobile turntables, scrapers, tools, etc. The Lansing Wheelbarrow Co. has enjoyed some thirty years of prosperity, and its well established plant is in excellent condition to properly care for this additional business. To care for their large general trade, they have warehouses in New York City, Philadelphia, Chicago, Kansas City, Minneapolis, St. Paul and San Francisco.

A NEW SHEET METAL CATALOGUE.

Catalogue No. 6 of the Willis Mfg. Co., Galesburg, Ill., is presented as an anniversary number, it being now twenty years since the Willis company began in a modest way the manufacture of builder's sheet metal goods. The present catalogue is practically an encyclopedia of sheet metal work, every conceivable article of that nature being listed in great detail.

The 180 pages show the highest grade of sheet metal store fronts, cornices, skylights, ventilators, fireproof windows, doors and shutters, fire escapes, ornamental iron work, shingles, metal ceilings, roofing slate, asbestos shingles, etc.

Galesburg is unusually fortunate as a railroad center, for the delivery of material to all parts of the country, and the facilities for manufacture and distribution has had much to do with their success.

NEW TOOLS.

Were it not for enterprising tool manufacturers, who realize the necessity for new tools, we should be still using the old fashioned tools of long past generations. Carried to extremes we should be threshing with the flail, and living without the many conveniences which labor saving machinery places within our reach.

Among the manufacturers who have kept well up with the times, is the Millers Falls Company, of 28 Warren street, New York City. This fall they are introducing a new Bit Guage, which clamps the bit securely at any point. A new hack saw frame designed for cutting steel rails, girders and large work generally, is particularly good in that an auxiliary handle may be placed anywhere on the frame, allowing two to use the saw, by placing the handle on opposite side—or one to steady it by placing the handle on the top of the frame. Drill brace No. 192 is arranged to do a variety of work under difficult conditions, the ratchets being arranged to allow the tool to be used as a breast drill. The gear is attached in such a manner that it can be instantly swivelled around to either side or in front of the brace for working in cramped position, or it can be detached entirely, when the tool becomes a ratchet brace with 10-inch sweep. It seems needless to say it is ball-bearing.

Possibly the greatest interest will concern the automatic star pocket borer No. 8, which possesses all the good characteristics of the regular borers in addition to its compactness. The handle contains 8 drills and a small screw driver, each in a separate compartment, so there is no trouble selecting the size wanted.

We understand that the mention of the NATIONAL BUILDER will secure any desired information regarding these or other tools made by the Millers Falls Company.

MORRILL'S SAW POINTS.

Recognizing the fact that the great majority of carpenters lack a complete understanding of the proper methods of jointing, setting and sharpening saws, but are willing to learn, Mr. Chas. Morrill, 275 Broadway, New York City, has prepared a short, but excellent, booklet on the subject. Probably no one is much better posted on the good points of various makes of saws and what they require to keep them in condition, for his long experience in making saw sets qualifies him to write with authority on the subject of the proper treatment of saws.

The reader finds a carefully written set of instructions which will enable him to sharpen the various kinds of saws, rip, cross, two-man, cross-cut, circular, hand saws, etc., each being treated separately. The illustrations aid materially in the instructions. As an article on saw setting would not be complete without a description of the Morrill saw set, a few pages are added describing this necessary tool.

We are advised that the booklet will be sent free to all mechanics and users of saws, and we would suggest that you mention the NATIONAL BUILDER when sending in your name.

COMPO BOARD.

In the use of natural materials, the builder has much to contend with. Lumber is subject to shrinking and swelling with the moisture, ordinary paper soon becomes worthless when exposed to the frost or dampness. Many cements require special treatment to render them available. Our modern necessities are such that perfect materials are required, and it is only by careful selection of materials and manufacture that they can be obtained.

For the purpose of lining walls, temporary buildings, and garages, covering old plaster, partitions, trimming windows, displaying fixtures, making portable booths, packing boxes, shirt-waist boxes, furniture, show cases, book cases, bulletin boards, and a thousand other places where a thin, light, durable surface is required, Compo-Board seems to be especially adapted. As it is built up of five layers, there is little or no tendency to be affected by moisture or the weather, and as it can be obtained in sheets much larger than lumber, it is available for every place where thin boarding could be used, and many others which readily suggest themselves.

In the manufacture of Compo-Board, the Northwestern Compo-Board Co., 5776 Lyndale Ave., Minneapolis, Minn., have eliminated as far as possible every tendency of the materials to deteriorate. The core is built up of narrow strips of thoroughly seasoned wood, the grain arranged indiscriminately, which overcomes the tendency to shrink, swell, warp or twist. This core is given a heavy coat of cement on both sides, which keeps all moisture and air from the wood, and the whole faced with a specially prepared moisture proof paper. The assembled layers are then subjected to a very heavy pressure and intense heat, making a straight sheet four feet wide and eighteen feet long.

While Compo-Board is sold through dealers generally, the manufacturers are sending out very interesting reading matter describing some of the many uses to which Compo-Board is adapted, and it would be well for all really interested to write them.

Where the Big Bargains Come From

Out from these great concrete warehouses come the greatest millwork and lumber bargains that the American market affords.

Our whole business revolves around the bargain idea. The present building season finds us better equipped than ever before to save money for contractors and builders: You will be amazed to see the big reductions on staple millwork and lumber of highest guaranteed quality.

New Bargain Catalog Ready

This catalog is in itself an immense exhibit of the finest building material on the market. It offers an almost unlimited variety of the latest styles in millwork of every description. Doors in all regular sizes and in scores of new and beautiful patterns and in various woods—veneered doors in Colonial, Mission, Craftsman and other popular styles—art glass doors in exquisite designs and colors—doors for every purpose. Windows to correspond with every style of door. Mouldings, inside finish, flooring, mantels, stair and porch material—everything that goes into any home, down to the very last detail. A bargain price and a guarantee of quality safe delivery and satisfaction on every item. Send for the catalog and see for yourself.

New Plan Books—Just Out

The new Gordon-Van Tine Book of Plans, prepared at a cost of over $5,000, is now ready for free distribution to carpenters and contractors. A complete and practical work that gives 32 designs for city, suburban and country residences, cottages and bungalows costing from $600 to $6,000. Also 12 plans for barn, dairy and cattle barns and other outbuildings. **This book keeps cost within original estimates,** for every plan has been proved again and again by actual construction.

The Plan Book will be mailed free on receipt of 10 cents in stamps or a dime to cover cost of packing and mailing.

You Are Invited to Visit Our Vast New Millwork and Lumber Plant

Although we conduct our business entirely by mail, we like to have carpenters and contractors visit our plant. Hundreds of them do this every year. Our warehouse is the busiest place in Iowa. Come and see us loading 22 cars at a time from our loading platforms, extending the entire length of the plant. Meet personally the men who stand behind this gigantic enterprise. The latch-string is always out.

NORTHWESTERN GRILLE WORKS
Office and Showroom, 1824 Milwaukee Ave., CHICAGO

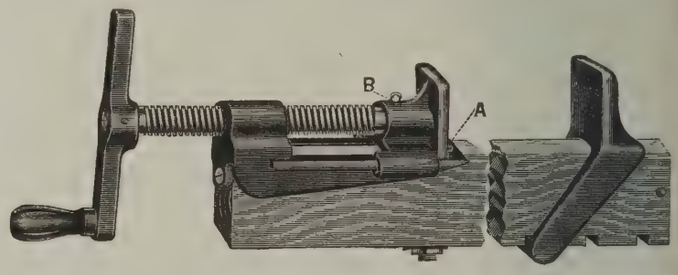
CARPENTERS AND CRAFTSMEN CLAMPS.

The manufacture of tools, and appliances for shop work calls for the highest grade of workmanship. A little glue, a few extra bolts or screws might patch up a piece of work going to a distant state when the article is one in which appearance is the main object. With tools and shop appliances, however, the material must be the best and the workmanship the most skillful to produce apparatus which will stand the wear and tear of continuous service, abuse at times, and do the work for which they are designed, quickly, economically and satisfactorily.

In no line are more exacting conditions met with than in the assembling manufacturers of woodwork. The quality of the material varies considerably, conditions are not always the same, and inaccuracies of workmen must be contended with. In assembling woodwork, such as doors, benches, furniture, etc., clamps are almost indespensible. Upon their pressing power depends the neatness of the work, and when once screwed up there must be no slipping, sliding, or twisting out of place.

When the E. H. Sheldon and Co., 321 N. May street, Chicago, Ill., commenced the manufacture of benches for manual training and craftsmen, they realized the necessity of a better grade of clamp than was then in the market. From their own designs, they made clamps which proved peculiarly efficient in their work. The constructive features appealed so strongly to all who saw them that they have added a number of patterns designed for special work. We show two forms of these clamps, from which a clear idea of their efficiency may be obtained. Among the features of the first, the following will be noted:

A steel collar entirely surrounds a groove in the end of the screw, making it impossible for the head to become detached from the schew. See "A."



The wide sleeve enveloping the bar eliminates all bending strains on the screw and holds the head rigidly in position. See "B."

An indestructible latch is cast into the saddle and engages in a tempered steel notch in the bar. The clamp may be used in a single position a million times without cutting loose or slipping. See "C."

The screw head is driven and headed on to bar before pinning, insuring absolutely permanent alignment under any pressure. See "D."

These clamps are made for the heaviest shop service. For ordinary cabinet work a hard maple bar is used in place of the steel. This model is shown in the second cut.

The prominence given these clamps might mislead one regarding

the class of goods made by E. H. Sheldon & Co. Besides these clamps they are well known for their lathes, manual training benches and vises, now so generally used in making craftsman and Mission furniture and fittings. E. H. Sheldon & Co., will be very glad to send their catalogue to anyone interested, and we believe that includes every NATIONAL BUILDER reader.

SILL AND STEP MOULDS.

Concrete block manufacturers early found that their particular machine was not the panacea for all the ills of building. Various forms of blocks might be made on any number of machines, but there came times when no machine was fitted for the work in question. One

of these cases occurs in the casting of long sills, lintels, steps, coping, etc. The difficulty was generally overcome by making plank frames which answered the purpose fairly well for one job, but another job required another frame.

It was to eliminate this trouble that W. E. Dunn & Co., 4135 Fillmore street, Chicago, Ill., devised the all-steel form shown herewith. The illustration shows its use so plainly that no description is required beyond saying that by the use of suitable plates the faces, top, ends, etc., can be left with any desired ornamentation or finish.

W. E. Dunn & Co. are headquarters for many other ingenious labor saving devices for the concrete worker, and their catalogue explains their line fully.

WE HAVE BEEN ASKED:

"Are you interested in the carpenters and the Disston Saws they buy, even after you have their money?"

This is a question easily answered. Do you suppose for an instant that we could have retained our regular trade, constantly increased it, built up and maintained the largest and greatest works of its kind in the world, over a period of seventy-one years, had we not seen to it that the articles we sent out were "making good" and satisfying the user?

LARGEST PLANT IN THE WORLD.

We want to force home to you the important fact that our plant is by far the largest of its kind in the world, consisting of 58 buildings, covering 50 acres. We employ 3,500 men, and during almost three-quarters of a century—the period we have been in business—very little time has been lost by the employes. You must realize that it requires "some orders" to keep an establishment of this magnitude going.

There surely must be more than ordinary merit in that brand of goods which creates and satisfies the demand over a long period of time.

PROTECTS THE USER.

We certainly do want to know if any **Disston Brand Saw, Tool or File** does not stand up to our guarantee. That guarantee is sufficiently broad to protect the user on every reasonable point. If you have a Disston Saw, Tool or File that has failed you through any cause of ours, let us know, and we will see that you bear no loss on our account.

Each and every article bearing the name DISSTON carries a full warranty as to material and workmanship.

And this guarantee has been in force since the first Disston Saw was made.

There are millions and millions of **Disston Brand Saws, Tools and Files** in practical use all over the world, which are giving the highest satisfaction. Of course, you will appreciate that almost every individual has his own ideas and opinions and it is impossible to cater to each, particularly in cases where there may be prejudice; so our only recourse is to satisfy the majority. And this we have been doing for over seventy-one years—making the **goods of superior quality and after designs which have been demonstrated by practical use to be best adapted for the purpose.**

It is noteworthy, however, that where we have one complaint, we receive thousands of letters voluntarily testifying to the superior worth and durability of **Disston Brand Goods.** This speaks for itself.

Nevertheless, we are always open to conviction, and if a man has complaint to make about any of the Disston Goods, it is but fair and just to us that he enter the complaint; for it is by considering, fully digesting and going into the cause of the trouble, in addition to our constant experimenting and investigations, which enables us to so improve and perfect **Disston Goods** as to bring them up to the highest point of efficiency. When a man has occasion to find fault with any of our goods we do not consider it "a complaint," but a stimulation and a reason for increased vigilance in looking to the safeguarding of the high prestige we have achieved for the name **Disston.**

MOST PRACTICAL EXPERIENCE.

We have the experience—and broad experience at that—extending over seventy-one years, not only in the making, but in the using of tools. Think of the enormous size of our plant; think of its many, diversified departments and their ramifications—Steel making, Saw making, the making of various Tools, File making, Wood working departments, Machine Knife making, Machine Shop. Think of the enormous quantities of tools and materials we buy from the outside, and think of the great quantity of tools of our own make that we use. When you consider all these points, it will give you some idea of our experience in the manufacturing and use of tools. **And that experience we make COUNT in the perfecting of our manufacturing facilities and the increased efficiency of our own brand of goods.**

MADE FOR EFFICIENCY.

In the **Disston Brand Saws, Tools and Files** you have the advantages of the product of a progressive, up-to-date factory, the **largest in the world.** Where the goods are made throughout, from the making of the steel itself—the superiority of which has been demonstrated for the past fifty-six years—to the finishing operation; and each process is performed by mechanics of long experience and highest order of skill.

We want to say to you, and say it positively, that **Disston Goods are made not merely to sell, but for practical use.** All materials used are of highest grade; the steel is properly hardened, tempered, and ground under the Disston exclusive processes; each article carefully inspected at various stages of the work, and finished in a workmanlike manner. **We fully guarantee them to be of highest efficiency and unequaled.**

WE ARE INTERESTED.

Reverting to the question:—Yes, we are interested in the carpenters and all other users of our tools, as well as the tools themselves after they have been bought and put to use. For we take great pride in the successful results they have achieved in the working, and fully realize—have realized for years—that the world-wide reputation we have earned can only be maintained by furnishing goods of the highest efficiency.

THE COYNE TRADE SCHOOLS.

Truly the poet said, "In the bright lexicon of youth, there is no such word as fail" but just as truly, there are failures, not only in the old age, but middle age and youth. The advantages of education, even if free, are not available to those who must work for their very existence. When a college education is obtained, it is frequently difficult to find a position open to which the long and costly education is adaptable. And anyway, who does the actual work, the man in the office or the man in overalls?

To those to whom a college course is practically impossible through lack of early schooling, there is open the vast field of trades. No trades pay better than the building trades, and on this account bricklaying, plumbing, electrical work, and painting, decorating and paperhanging have been selected by the Coyne National Trade Schools as best adapted to the great army of men who would better themselves.

In the Coyne Schools, every effort is made to obtain natural working conditions. Students are not told what brick, mortar and trowels are, they are given the bricks and mortar and tools, and shown how to lay a neat, strong wall. Actual working conditions are used, the only difference being that, after the work passes critical inspection, it must be torn down to make room for the next day's work.

In plumbing the same general course is followed. Joints are wiped in the most approved manner, fixtures are set up and tested. Master plumbers inspect the installation before it is passed, and the student leaves the school prepared and competent to do any of the work in that trade.

Similar instruction in electrical work is given the student working on actual installations, and the finished work must conform to the Underwriters' Rules. When a graduate leaves the school, he is capable of filling a position as a regular electrician or of starting an electrical business of his own.

The schools also have courses in mechanical drawing, painting, decorating and paper hanging, in which the same thoroughness is followed.

One of the newest trades to be taught is that of moving picture operating. So general have these positions become that the competent operator is scarcely ever out of employment at good wages. As in the other course, the student works with standard apparatus, and is competent to accept a position immediately upon leaving the course.

As instructions of this character cannot be taught by mail, the students come directly under the eye of the instructors who, as practical workmen, can readily see the weak points in each student and so aid him by personal instruction. The nature of the work is such that no regular classes are formed, the student starting at any time and advancing as fast as his individual work allows.

For those who wish to learn a trade, there is probably no better place than the Coyne National Trade Schools. For those who wish to "brush up" and see what new ideas there are in construction and workmanship since their apprentice days, there is ample opportunity. To secure full information regarding the schools, write the Coyne National Trade Schools, 59 E. Illinois street, Chicago.

A visit to the schools is a most interesting trip, as students can be seen doing the actual work of these trades.

Amatite ROOFING

Mineral Surfaced
Needs No Painting

EVERYTHING about Amatite appeals to the man with common sense. He can see its superiority at once—the real mineral surface ***which never needs painting;*** the two layers of Pitch which is the greatest waterproofing material known; the two layers of heavy Tarred Felt—all these contribute to the popularity of Amatite.

We can make Amatite better and cheaper than anyone else on account of our greater facilities, and consequently we sell it at a surprisingly low figure.

Simply the fact that it needs no painting is enough to make a man sit up and take notice—especially the man who has spent time and money in painting and repainting smooth surfaced roofings.

Every dealer should push it.

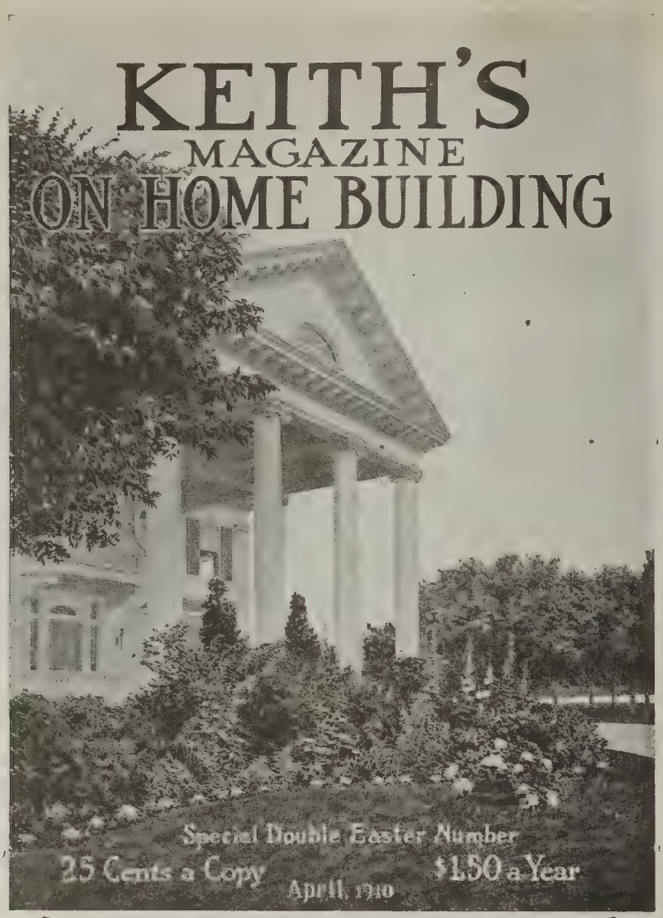
A CONTRACTOR'S REPUTATION AND

CORTRIGHT METAL SHINGLES

Many a builder or contractor has had his bid turned down, because he had acquired the reputation of using poor quality material.

This may not always be his fault, for his competition may be so keen, or the owner's funds may be so limited, as to necessitate some sacrifice in the quality of materials.



Cortright Metal Shingles are economical enough in cost to enable you to meet competition with superior instead of inferior quality, and at the same time possess so many obvious advantages over other forms of roofing that even should your bid, including them, run somewhat higher than competitors' you have arguments in their favor so convincing as to overcome any such differences.

Another reason why **Cortright Metal Shingles** would help you on competitive work is they are so constructed that any of your ordinary workmen can lay them, saving you the otherwise necessary expense of skilled roofers.

Write today for our special proposition to contractors and builders.

IT'S A SCRAPER BUT IT WORKS LIKE A PLANE

That is what the many satisfied contractors and builders who are using the **Boss Improved Floor Scraper** say.

The **gauge** on the front and wheels at the rear make it like a plane. This gauge, which keeps the knife from making a depression in the floor, gives the knife a double support. It can be set for **any thickness of shaving,** or **instantly removed** for working up into corners.

Deep Cutting is prevented by the pear shaped wheel in front, which lets the knife down gradually to make the cut.

Poor work is **impossible** as with the simple but positive adjustment of this gauge and wheel attachment the knife leaves no mark. The standing attachment cleans the wheel and takes off the rosin when working hard pine.

Price very low. Write for descriptive Circular "N"

Come to Roofing Headquarte

We Sell Direct From the Factory Every Dependable Grade and Kind of Prepa

SLATE SURFACED ROOFING AND SIDING

FIREPROOF — NO PAINTIN
Send For Free Samples.

Proof against action of fire, snow, ice, lightning and wind. Cannot crack, warp, split or decay. Made without tar. Impervious to water, cold and heat.

Can be laid over old shingles or tin on either steep or flat roofs.

The heavy coating of natural colored red or gray crushed slate is firmly imbedded in a 3½-ply fabric of long fiber felt, from 10 to 15 per cent heavier than any other rubber felt roofing manufactured. In its composition, weight, thickness and quality it is the same superior fabric we have sold for years and which has been tried and proven in every climate from Alaska to Texas. But the surfacing of slate in permanent colors is better than any surfacing heretofore produced, as durable and handsome as slate tile.

To secure a handsome color effect use Red Slate Surfaced Roofing for the roof and the Gray Slate Surfaced Roofing for the siding, with or without battens. The house thus finished will appear to be walled and roofed with stucco or cement.

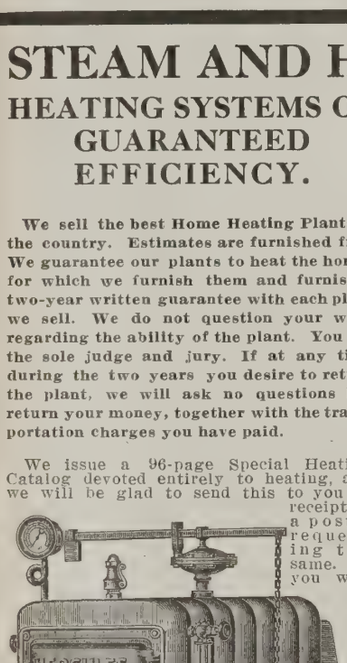
Substitute This Better Roofing For Shingles and Double Your Profits

Or you can cut in half the cost to your client of his roof and at the same time furnish him a roof that is guaranteed to outwear shingles and is far more attractive in appearance.

The illustration shows our Modern Home No. 144, roofed with Red Slate Surfaced Roofing and the second story sided with Gray Slate Surfaced Roofing. Cost of roofing (21 squares) for the second story and roof of this house, $47.25; cost of labor for laying, $6.30; total cost, $53.55.

A Grade Cedar Shingles (21,000) for the roof and second story of this house would cost $73.50; cost of laying shingles, $31.50; total cost, $105.00. Remember, our Red or Gray Slate Roofing will outwear shingles.

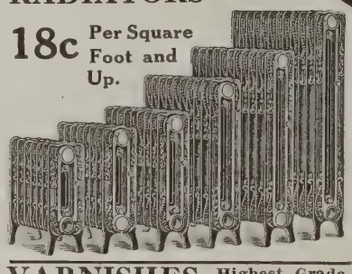
Total saving on material and labor through the substitution of this better roofing for shingles, $51.45.



STEAM AND HOT WATER HEATING SYSTEMS OF GUARANTEED EFFICIENCY.

We sell the best Home Heating Plants in the country. Estimates are furnished free. We guarantee our plants to heat the homes for which we furnish them and furnish a two-year written guarantee with each plant we sell. We do not question your word regarding the ability of the plant. You are the sole judge and jury. If at any time during the two years you desire to return the plant, we will ask no questions but return your money, together with the transportation charges you have paid.

We issue a 96-page Special Heating Catalog devoted entirely to heating, and we will be glad to send this to you on receipt of a postal requesting the same. If you will kindly make us a rough sketch of the building you intend to order a heating plant for, we will be pleased to furnish you an estimate on the boiler, radiators, all fittings, pipe and accessories for the complete installation of a steam or hot water heating plant.



$200.00 is what you would pay elsewhere for a high class guaranteed steam heating plant for the six-room house shown below as our Modern Home No. 103. We equip this residence with a complete steam heating plant, equal to any plant made in economy of fuel consumption and in heating capacity, for only $125.80, or we offer to furnish this same building with a complete hot water heating plant for only $158.36.

For the big eight-room house, also shown below and designated as our Modern Home No. 163, we furnish a complete steam heating plant for $193.64 or a complete hot water heating plant for $238.07.

We will make you the same proportionate saving on heating plants for the buildings you are erecting, no matter what their size.

COMFORT RADIATORS

18c Per Square Foot and Up.

VARNISHES, Highest Grade, One-Third Less.

We carry an enormous stock of Varnishes of every kind as well as paints, kalsomine, whitewash, wire and waxing brushes and other painters' tools. Thousands of painters and builders will not buy an ounce of varnish or paint elsewhere. Our prices for the very best qualities of varnish possible to produce are from 50 cents to $1.50 lower than retailers' prices.

Every ounce of paint and varnish material we sell is guaranteed to wear and give perfect satisfaction, or your money will be returned.

We have space for but three examples of our hundreds of cut prices in this line.

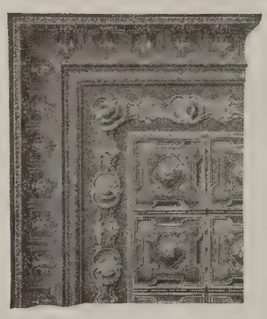
Our Roofing Catalog describes the largest line of Roofings carried by any one Supply House in the country, including Gravel Burlap, Marble Coat, our famous Best-of-all, Flint Surfaced Asphalt and Century Tarred Roofing. Pressed Standing Seam, Crimp, Corrugated Steel Roofing, as well as building and sheathing papers, deadening felts, plaster board, metal lath, eaves trough, conductor pipe, metal shingles, siding, etc.

COMPOSITION ROOFING



Flint Sand Coated Rubber Roofing. Unequaled Value at Our Low Price.

Many a roll of Composition Roofing identical in quality with ours has been sold by others under some fancy label at two and three times our price.

While our Composition Roofing has not the durability or the handsome appearance of our Slate Surfaced Roofing, and other more expensive grades, it will fully meet the requirements of the builder who desires only a temporary roofing to last for a few years. Our Composition Roofing is made of standard felt, saturated with an asphaltic composition and is finished on one side with a smooth asphalt rubber coating and on the other side is coated with fine sand. It may be used with either side exposed to the weather.

One-Ply.	Weight, 34 pounds. Per Roll.....	$0.75

Three-Ply.	Weight, 54 pounds. Per Roll....	1.05

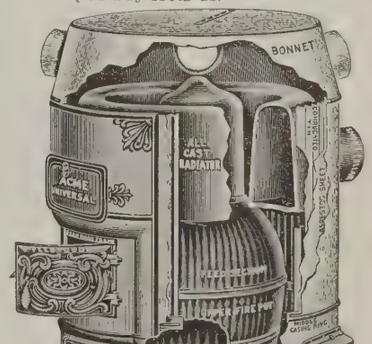
METAL CEILINGS.

There are good reasons for the increasing popularity of Metal Ceilings. In new buildings they are actually cheaper than lath and plaster, while at the same time more sanitary and durable. Their decorative possibilities are apparent at a glance. No matter how great the demand for any kind of building material, we do not add it to our line until we have perfected arrangements to sell it to you direct from the factory at one profit.

So complete is our line of Metal Ceilings that we are obliged to publish a special catalog to do it justice. Every favored design is included in our line—Renaissance, Louis XIV, Empire, Colonial and other styles. Send for our free Metal Ceiling Catalog and be ready to seize the additional money making possibilities the demand for this material offers. The laying of a metal ceiling is now considered a carpenter's work.

WARM AIR FURNACES

$25.11 AND UP



Send us your blue prints. Let us figure on your furnace needs. We will gladly abide by the result of your price and quality comparisons.

So large is our business in heating plants that we are able to maintain a corps of heating and ventilating engineers whose services are at your command without cost.

As a mere suggestion of the savings we can effect for you we call your attention to Modern Home No. 103, illustrated at the foot of this advertisement. We equip this six-room house with a complete Warm Air Heating Plant for soft coal for $61.55 and for hard coal for $64.55.

A complete soft coal Hot Air Heating Plant for Modern Home No. 163, also pictured below, is sold by us for $85.41, while the same plant designed for hard coal costs only $88.79.

Figure for yourself the savings we make you and remember we guarantee absolute satisfaction or your money back on any furnace you buy from us.

THE GREATEST WORK

ever published on Architecture, Carpentry, Contracting, Building and all allied branches is the new 10 volume edition

Cyclopedia of

Architecture, Carpentry & Building

Ten massive volumes; 4,670 7x10 inch pages; 3,000 full-page plates, detail drawings, plans, color plates and photos of buildings completed and in course of construction. Bound in half morocco leather and printed on special enameled paper in large, clear, readable type. Titles beautifully engraved and stamped in 23 carat gold.

No work so comprehensive, so authoritative, has ever before been placed on the market. This great work is a complete review of architecture, carpentry and building. Every problem likely to confront you in your daily work is solved and the solution placed before you in such a clear manner that you cannot fail to understand and profit by it.

Just examine the "Partial List of Contents" below and you will at once realize how broad is the scope of this work—how thoroughly it covers the building trades.

PARTIAL LIST OF CONTENTS

Reinforced Concrete—Contracts and Specifications—Building Materials—Carpentry—Building Superintendence—Estimating—The Law of Contracts and Liens—Masonry—Stair Building—Heating—Ventilation—Hardware—Steel Construction—Elevators—Architectural Drawing—Freehand Drawing—Blue Printing—Greek and Roman Orders—Water Color Hints for Draftsmen—Painting—Wiring of Door Bells—Sheet Metal Pattern Drafting—Mechanical Drawing—Lettering—Shades and Shadows—Rendering in Pen, Ink and Wash, etc.

READ OUR LIBERAL OFFER

THEN SEND THE COUPON

To prove our absolute confidence in the superiority of this work over all others, we make this liberal offer: Upon receipt of the coupon in the lower right hand corner, we will place the entire cyclopedia of ten volumes in your home or office—you keep the books seven days—examine them thoroughly, critically—subject every formula and problem to a severe test. If you are satisfied, send $2.80 after examination and $2.00 every month until you have paid the special $24.80 price. The regular list price is $50.00. As a further guarantee, we will remove the books at our expense if you are not satisfied. We pay all express charges. The books are compiled from the instruction papers of the American School of Correspondence. If you are interested in our Building Courses, mail the Coupon at the left. It will bring full information and valuable advice by mail at once.

We Have an Attractive Proposition for One Carpenter or Builder in Every Community to Take Orders for Our Widely Advertised

EDWARDS' METAL SPANISH TILE

ARE EASILY SOLD BY OUR AGENTS

Home Owners Everywhere Are Reading Our Advertisements in the Leading Magazines

EDWARDS' INTERLOCKING METAL SPANISH TILE

ARCHITECTS EVERYWHERE SPECIFY THIS ATTRACTIVE ROOFING

Edwards' Metal Spanish Tile are stamped out of the highest quality Worcester Grade Terne Plate, size 10 x 14 inches, furnished either painted or heavily galvanized. They are provided with our patented interlocking device, which conceals all nails, makes it possible to get a perfectly moisture proof roof without **soldering** and without danger of having the tile crack open in extreme cold or hot weather.
Edwards' Metal Spanish Tile looks exactly like the best Terra Cotta Tile. They have the decided advantage of being much lighter, easier to apply, longer lived and cost much less.

Write us today about your territory. Here's an opportunity you should not miss. Many carpenters and builders have been so successful taking orders and laying our Metal Spanish Tile that they now devote their entire time to this business. Others have made big profits selling and laying our metal tile roofing "between jobs." We show you how to build up an independent, profitable business in your own community. Write for our proposition today. The territory is going fast. Don't be too late. Send a postal right now.

BRAIN OR BRAWN

YOU EARN your bread with brain and skill rather than with muscle. Otherwise you would be a laborer with pick and shovel, instead of a mechanic with a kit of fine tools.

One day two husky laborers were told to remove a few yards of paving bricks between street-car tracks. They began hammering them to pieces with sledges. Hard work—slow work. Not until they were shown, did they think of loosening the bricks with bars and pulling them out. ALL BRAWN—NO BRAIN.

You use your brain to save your brawn, to save time, to save mistakes, to save you money. And you never make a more profitable use of your brain than in the selection of the saw, for it is the tool that you use most—the tool requiring most energy and most skill in handling. The intelligent mechanic uses

ATKINS SILVER STEEL SAWS

These saws are fully abreast of the times. They embrace the latest and most scientific ideas in saw making. They are so constructed that they run easier than any other saw, and the SILVER STEEL used in the blades will receive that keen, sharp, cutting edge that you high-class mechanics want—and hold it.

How to Get Them

Go to your dealer and tell him that you are a progressive mechanic and you want tools that will save you time and strength. Select a saw with the words SILVER STEEL on the blade. Then you'll be sure of getting a saw representing the highest achievements in saw making. If your dealer does not sell them he will order for you from his wholesale house. If he won't do this, then let us know. We'll help you get the finest saw if you want it.

You Run no Risk

We stand back of every SILVER STEEL SAW with a guarantee so strong that you risk nothing—not one cent. If the next saw you buy is an Atkins saw and if the words SILVER STEEL are on the blade, remember that it is guaranteed to run easier, cut faster and hold its edge longer than any other saw. If it is not absolutely satisfactory, you are authorized to take it back to your dealer and get your money back or a new saw. If he won't refund your money, let us know.

Offer to Carpenters.

We are compiling a list of high class mechanics and if you will send us your name, we'll mail you our book on saws free of charge. If you'll send us ten cents to pay postage, we'll forward you free a strong, durable nail apron, our Saw Sense book, monthly time book, and a whole lot of useful information about high grade saws.

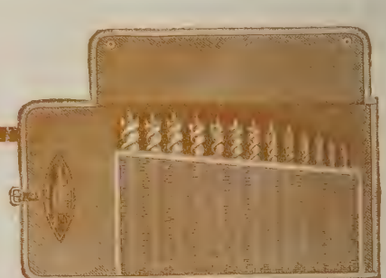
Disston Saws, Files and Tools

For fifty-six years we have been making Disston Crucible Steel. It is made under the exclusive Disston process. The long life and cutting properties of Disston Saws are due to Disston Crucible Steel and the treatment it undergoes in our shops.

The Disston establishment is the ONLY ONE making steel for its full line of saws and tools—one reason why Disston Saws are uniformly durable and efficient.

Disston Saws are hardened and tempered by the exclusive Disston process.



It pays to buy Disston Saws and Tools. For any and every kind of work Disston Saws, Files and Tools are the most reliable.

We have been making saws for over seventy-one years.

BISHOPRIC WALL BOARD AND SHEATHING

BISHOPRIC Wall Board is cheaper and better than lath and plaster. It is the ONLY Wall Board COMBINED WITH LATHS and Asphalt Mastic. Laths are necessary in a Wall Board, just as they are in plaster walls, to prevent warping and to insure solid, rigid, stiff substantial

WALLS AND CEILINGS

Bishopric Wall Board Easily Applied

Bishopric Wall Board also is the only Wall Board with a waterproof body. The Asphalt Mastic in which the laths are imbedded affords absolute protection against dampness. Does away with delays in building. Applied winter or summer. Is nailed to studding dry, ready for immediate application of paper, paint, burlap, or any other kind of decoration.

Bishopric Wall Board is made of kiln-dried, dressed laths imbedded in hot Asphalt Mastic, surfaced with sized cardboard and cut in the factory into 4x4 ft. sheets. Shipped in crates ready for immediate nailing to studs. It is guaranteed not to swell, shrink, warp, crack, flake or blister. It is clean, sanitary and odorless; proof against moisture, cold, heat, and vermin; saves fuel and keeps out summer heat; also deadens sound.

It is suitable for dwellings, factories, new partitions in old buildings, finishing attics, porches, laundries, cellar ceilings, garages, etc.

Shows Construction of Bishopric Wall Board.

PRICE WALL BOARD AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6.40 per crate, or $2.50 per 100 square feet, f. o. b. New Orleans, La., Cincinnati, or Alma, Mich. We ship from nearest point.

T. W. Hanes, Carpenter and Contractor, Mounds, Ill., wrote August 15: "I have used 13 crates of Bishopric Wall Board, and the waste could be put in a hat."

Wm. Cooper, Taxidermist, Milo, Me., March 9, wrote the Philadelphia Farm Journal: "Your interesting paper has been a real bonanza to me. I wanted a cheap, warm method of lining my new work room. An advertisement in your paper gave me the very idea and material at a price that suited my pocket. I wrote to two firms who advertised with you, but selected 15,000 ft. of sheathing from the Bishopric Wall Board Mfg. Co. of Cincinnati. If the stuff was made on purpose, it could not suit me better; and a most prompt, obliging firm they are, too."

Cheaper Than Lumber. Saves 75% on Labor. Does away with Building Paper.

BISHOPRIC SHEATHING

Ideal Material for Cement Buildings or Stucco Exteriors. Proof against Dampness.

Bishopric Sheathing is made of same materials as Wall Board, but finish is not necessarily so fine, therefore costs less. It is of uniform thickness, insuring a perfectly even surface when applied.

Bishopric Sheathing is nailed to studs, with lath and asphalt side exposed. Over laths, weather boards are nailed or cement applied.

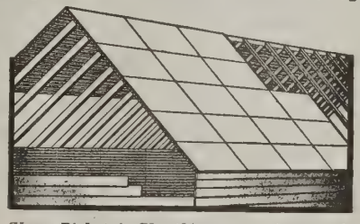
Shows construction of Bishopric Sheathing.

Arrow points to Asphalt Mastic into which laths are imbedded.

Bishopric Sheathing makes a more solid and substantial wall than lumber. There are no gaping joints; no widening cracks due to shrinkage; no knot holes.

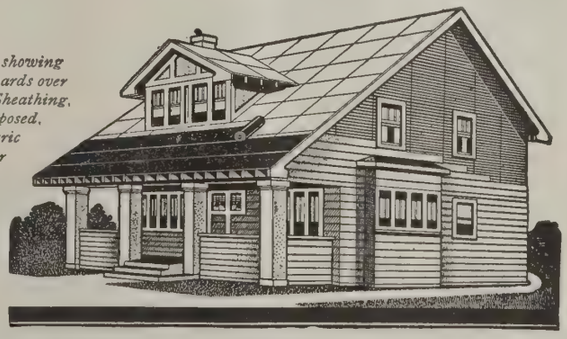
The Asphalt Mastic in Bishopric Sheathing is a non-conductor, moisture cannot penetrate it. It is proof against vermin. The pests cannot bore through the tough, gummy Asphalt Mastic. In applying weather-boards over the laths, dead air space is left between the laths forming splendid insulation. Does away with the expense of building paper and cost of its application.

Wall Board and Sheathing are shipped in crates



The cost of applying Bishopric Sheathing is but $2.50 per 1000 feet—A SAVING OF ABOUT 75 PER CENT. Furthermore, 1,000 square feet of wood sheathing covers but 750 feet of surface, 20% less being due to tongue and groove. In Bishopric Sheathing 1,000 square feet covers 1,000 square feet of space

Bishopric Sheathing insures comfort during the construction of the building. As soon as the building is closed in with Bishopric Sheathing, the men may work in comfort on the inside during bad weather, finishing the outside on suitable days. This insures continuous work, without loss of time, enabling the contractor to hold his men and complete the work in the least possible time.



Bishopric Sheathing is used with equally splendid results under flooring and as a substitute for roofing boards. Used under floors, it serves as a sound deadener and keeps out dampness; used under the shingles, it keeps out summer heat.

ITS MANY USES—Bishopric Sheathing also is used with excellent results as a lining for dairy barns, ranch houses, poultry houses, driving stables or any out-door building where protection from the elements, Summer or Winter is desired.

Bishopric Sheathing is the ideal material for cement exterior or stucco work. Cement firmly adheres to the laths and Asphalt Mastic and makes a solid, smooth exterior. For factory or residence this form of cement or stucco construction is the cheapest and best known.

Shows Bishopric Sheathing over rafters ready for Bishopric Roofing, also Weather-boards over Bishopric Sheathing.

Ideal home showing Weather-boards over Bishopric Sheathing, lath side exposed, also Bishopric Roofing over Bishopric Sheathing. (smooth side of sheathing exposed)

PRICE SHEATHING AND SHIPMENT — Crate of 16 sheets, covering 256 square feet of surface, $6, or $2.35 per square of 100 square feet, f. o. b. New Orleans, La., Cincinnati or Alma, Mich. We ship from nearest point.

Write for Descriptive Booklet and Samples of Bishopric Wall Board, Bishopric Sheathing and Bishopric Roofing—All will be sent free.

No Rubbing Needed for a Beautiful Flat Finish

Johnson's Flat Wood Finish, applied with a brush, produces the soft, velvety effect of the hand-rubbed finish at one-third the cost for labor. All that is necessary to obtain this beautiful flat finish on any woodwork, new or old, is to brush on a coat of Johnson's Flat Wood Finish. It dries in an hour without a suggestion of gloss.

Architects, Contractors, Painters and Home Owners everywhere are enthusiastic over the results obtained with it and the big saving it makes possible.

Johnson's Flat Wood Finish

is a liquid—an easy spreading preparation—manufactured especially for finishing interior woodwork of new residences and buildings—as well as furniture—and equally valuable for refinishing old surfaces.

This flat wood finish opens a new field for the painter. He can now give his customers the beautiful, artistic, flat, hand-rubbed effects that have always been so high-priced on account of the labor—at prices that are within the reach of everyone.

By the use of Johnson's Flat Wood finish, you can make figures on hand-rubbed effects that will land the contract every time—give your customer perfect satisfaction and make you a good profit besides.

For giving this rubbed effect to new woodwork, apply Johnson's Flat Wood Finish over Wood Dye, Paste Wood Filler, or Varnish—for old woodwork or furniture having a gloss or varnish finish, simply apply a coat of Johnson's Flat Wood Finish. It is not necessary to remove the old finish before applying the new—and one coat *thoroughly brushed in* is sufficient.

Prices of Johnson's Flat Wood Finish

Gallons	$3.00
Half Gallons	1.60
Quarts	.85
Pints	.30

One Gallon is sufficient for 500 square feet

FREE Let us send you free a test can of Johnson's Flat Wood Finish and a copy of our Instruction Book. Edition NB10. We want every painter—you—to know all about this most important development in wood finishing materials. We will send you a free sample so you may try it yourself at our expense and be convinced. Write today or fill out coupon for sample of Johnson's Flat Wood Finish and panels of wood finished with it.

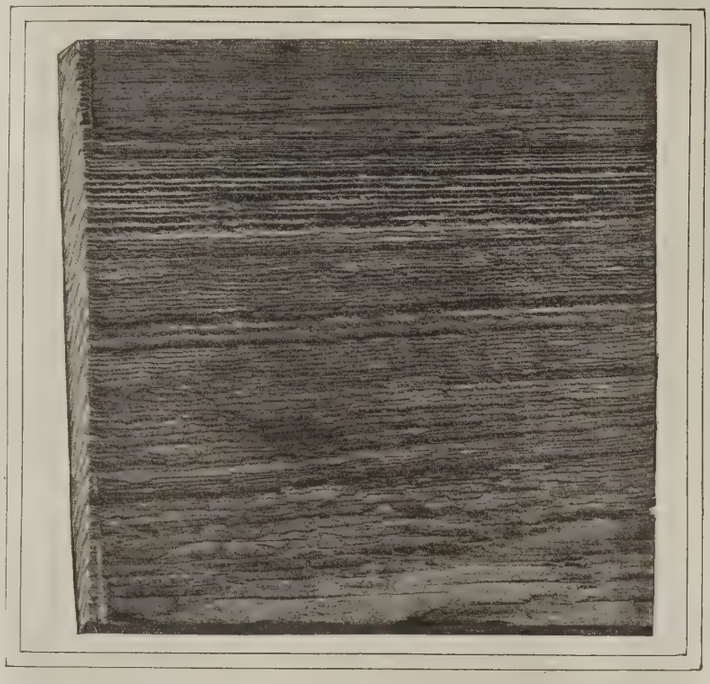
issued June 30, 1911, says of

CYPRESS:



"AS SIDING IT PRACTICALLY WEARS OUT BEFORE IT DECAYS"

(FROM PAGE 44, U. S. GOVERNMENT BULLETIN 95.)

Same report says "CYPRESS shows paint well and holds it for many years, but lasts a long time without it."

(You know the conservatism of Government Reports)

Here's a photograph (straight from the wood) of a piece of *Cypress Siding* taken from St. Charles College, La., duly attested in writing by the president, Father Maring. Built 1819—torn down 1910. *NOT A TRACE OF ROT.* Note that the lower or exposed edge, originally the thicker, has become the thinner by the simple erosion of nearly a century of rains.

CYPRESS SIDING SOUND AS A DOLLAR after withstanding the tempests of a century and willing to start again! *91 YEARS "ON THE JOB," WITHOUT EVEN PAINTING,* on a church in use till the day it was razed to make room for a larger building, and the *CYPRESS LUMBER COMPOSING IT THEN USED AT ONCE* to erect a new gymnasium!

THERE'S INVESTMENT VALUE WORTH WHILE!

WRITE TODAY for VOLUME ONE of the CYPRESS POCKET LIBRARY, with FullText of OFFICIAL GOVT. REPORT as quoted above. (Sent FREE PROMPTLY on request.)

"WOOD THAT WILL STAND THE GREENHOUSE TEST WILL STAND ANYTHING." *ASK FOR VOL. THREE ALSO—FULL OF VITAL FACTS.*

When planning new improvements or repairs to old ones, just remember—"*With CYPRESS you BUILD BUT ONCE.*"

Let our "BUILDERS' HELP DEPARTMENT" help YOU. Our entire resources are at your services with Reliable Counsel.

EVERY OBSTACLE OVERCOME

The Acme Floor Scraping Outfit.

No more floor scraping worries. No more unnecessary loss of time or money when the *Acme Floor Scraping Outfit* is on the job. One man and the *Acme* can do the work of four men using hand scrapers. Think of the saving of time this means to you. If you use the outfit on one good sized floor scraping job, you have saved enough in labor to pay for the machines.

This is a fact, and I am ready to prove it by offering to ship the *Acme Floor Scraping Outfit* to you on *one week's free trial* at my expense. You can give the machines as severe a test as you know how and then decide for yourself if you want to keep them or ship them back.

If you want my booklet describing this outfit and further particulars, drop me a line to-day and details will be forthcoming by return mail.

JOSEPH MIOTKE

249 Lake Street MILWAUKEE, WIS.

WE WANT TO SEND YOU A SAMPLE

We want every carpenter and builder and home owner in America to know about and to have a sample of

UTILITY WALLBOARD

It is to your interest to have this sample and to become thoroughly familiar with this remarkable material.

Utility Wall Board marks the greatest advancement that has been made in interior building construction in a hundred years.

It is made of fibre—very hard and tough and durable. It is waterproofed on both sides. Being a non-conductor, it is largely heat and cold and sound proof.

It is very easily put on—nailed right to the studding and takes the place of both lath and plaster.

It is the only wall board on which you can safely use wall paper. At the same time it lends itself admirably to tinting and stenciling, or other forms of decoration. Made in various widths and lengths to meet all requirements of interior finishing.

Write today for the sample and for the new book of interiors.

Utility board is sold through dealers in builders' supplies everywhere.

6 Months' Free Trial

Hand and Foot Power

Mechanics' Special—
will not draw temper

Don't take our word that this tool grinding, buffing and polishing outfit will save money for *you*. We offer you 6 months' absolutely *free use* of this outfit in your own work on your own tools, and let you prove for yourself that it is a money-saving and money-making outfit for any tool user. Use it a whole half year free, and if you don't find it a money-maker for you, send it back. The half year's use will not cost you a cent. If you want to make your own work and the work of the men you hire count for the most profits, how can you neglect this liberal offer? Return the coupon at bottom of page for 6 months' free trial offer.

Luther Tool Grinders

6 times faster than emery wheels
25 times faster than grindstones
Built like a high grade lathe

Special attachments enable inexperienced persons to sharpen Chisels, Twist Drills, Etc.

The genuine Carborundum wheels will not draw temper from tools; no need of cooling with water—all your tools will last longer, which means that much money saved. The wheels cut hardest steel as emery does soft copper—it is only a moment's work to do any job of tool sharpening, so easy in fact that tools are always kept razor-keen and that means more work accomplished with less effort, which means more money saved. The wheels outwear any number of emery wheels and that means another money-saving.

11 Tools in One

consisting of Mechanic's Special, built like a high-grade lathe, with steel and malleable construction, machine cut spur gears, bronze bearings in oil bath, etc., and the following accessories: rough Carborundum wheel, fine Carborundum wheel, 1 chisel attachment, and 1 twist drill attachment by which inexperienced persons can sharpen chisels and twist drills, 1 polishing spindle, 1 buffer, 1 polisher, 1 oil stone, 1 Carborundum hone in leather case, 1 Carborundum scythe stone, 1 foot-power attachment.

Return this Coupon for 6 Months' Free Trial Offer

This perfected sharpening, polishing and buffing Mechanic's Special Outfit is a business and labor economy—can you afford to neglect our liberal offer? Return this coupon for 6 Months' Free Trial Offer, and free booklet reprinting the story of Carborundum as it appeared in McClure's Magazine.

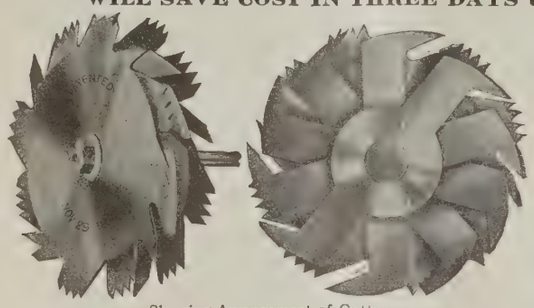
Oak Flooring

Every **builder, owner** and **investor** should insist on OAK FLOORING. Its natural beauty combined with its **economical** and **durable qualities,** makes it the **King** of **Flooring.** Any truthful landlord or architect will tell you that OAK FLOORING **increases** the **renting** and **selling values** of any building more than any other kind of Flooring.

OAK FLOORING will harmonize with any kind of trim and is susceptible to any kind of finish. It is **rich** and **cheerful** in color, and imparts an air of refinement and elegance to a home.



OAK FLOORING ¾" thickness by 1½" or 2" faces can be laid over old floors or over cheap sub-floors in new homes at a very low cost. It is cheaper than carpets or Pine Flooring.

OAK FLOORING is made in four grades in the 13/16" thickness and two grades in the ⅝" thickness. It is adaptable for the humblest of homes or a palace.

Write us for further information.

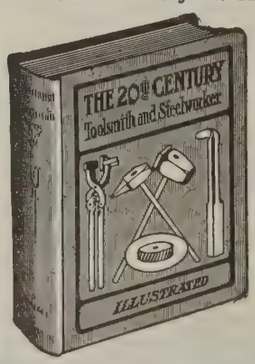
USEFUL BOOKS FOR CONTRACTORS

PRACTICAL UP-TO-DATE PLUMBING. By George B. Clow. 310 Pages, Over 250 Illustrations, Large 12mo, Cloth. Price.....$1.50

A practical, up-to-date work on Sanitary Plumbing, comprising useful information on the wiping and soldering of lead pipe joints and the installation of hot and cold water and drainage systems into modern residences. Including the gravity tank supply and cylinder and tank system of water heating and the pressure cylinder system of water heating. Connections for bath tub. Connections for water closet. Connections for laundry tubs. Connections for wash-bowl or lavatory. A modern bath room. Bath tubs. Lavatories. Closets. Urinals. Laundry tubs. Shower bath. Toilet room in office buildings. Sinks. Faucets. Bibb-cocks. Soil-pipe fittings. Drainage fittings. Plumber's tool kit, etc., etc. The composition and properties of solder and how to make it, are carefully treated and a chapter is devoted to useful information. There are given a large number of valuable tables giving the pressure at different elevations, capacity of pipes, etc. The work also contains over fifty carefully prepared drawings, giving complete piping connections for home, tenement and office buildings.

MODERN ESTIMATOR AND CONTRACTOR'S GUIDE. FOR PRICING ALL BUILDERS' WORK—WITH MANY TABLES, RULES AND USEFUL MEMORANDA. By Fred T. Hodgson, F. A. I. C. 318 Pages, 100 Illustrations, 12mo, Cloth. Price.....$1.50

One of the most desirable books for the general builder to have, is a good and reliable work on estimating; and we are certain the book we are now offering, if the large number of favorable testimonials and press notices we have received is any indication, is one of the best, and most reliable books on the subject that has ever been published on this continent—or any other for that matter. We have no hesitation whatever in recommending this book to our patrons who want a good work on estimating. The work gives a lengthy and clear explanation of the several methods employed in estimating, among which may be mentioned, "Estimating by comparison," "Estimating by the cubic foot," "Estimating by quantities," "Estimating in detail," and several other systems.



HOT WATER HEATING, STEAM AND GAS FITTING. By Wm. Donaldson. Large 12mo, 250 Pages, Over 100 Illustrations, Cloth Binding. Price.....$1.50

A modern treatise on Hot Water, Steam and furnace Heating and Steam and Gas Fitting, which is intended for the use and information of the owners of buildings and the mechanics who install the heating plants in them. It gives full and concise information with regard to steam boilers and water heaters and furnaces, pipe systems for steam and hot water-plants, radiation, radiator valves and connections, systems of radiation, heating surfaces, pipe and pipe fittings, damper regulators, fitters' tools, heating surface of pipes, installing a heating plant and specifications. Plans and elevations of steam and hot water heating plants are shown and all other subjects in the book are fully illustrated.

The closing chapter, devoted to useful kinks, contains information on a variety of subjects which will be found of interest and value to the workman, as will also the many useful tables given at the end of the volume.

THE 20TH CENTURY TOOLSMITH AND STEEL-WORKER. By H. Holford. 240 Pages, 120 Illustrations, 12mo, Cloth Binding. Price.....$1.50

This book is written in the interests of all mechanics connected with the working and manufacture of steel into tools, and gives all the secrets and obstacles to be overcome towards making steelwork or toolmaking a success. It will be invaluable to the young mechanic and place him years in advance of his fellow workman, by the reading and a little reflection of its contents.

It is not comprised of quack theories or foolish ideas, and is not written by a college student, who knows nothing except what he has been told or gathered up from papers and periodicals. But is written by a thorough expert mechanic who has spent the best part of his life over the anvil with the hammer and tongs.

"AMERICAN"
TILTING TABLE BAND SAW

In the design of the "American" Tilting Table Band Saw we have adopted every improvement, every up-to-date time-and-labor-and-money-saving detail which experience has shown to be requisite to saw success.

If your experience has been limited to the use of the average band saw you will know in a moment the value of such a machine as we have made in the "American."

An "American" Band Saw should be in every woodworking shop where the best work at the least cost in the shortest time is the ideal sought.

You can have your choice of two sizes in the "American"—27 or 36 inch—and whichever you buy, you can expect more from it than from any other band saw you ever used.

Taylor Portable Steel Derrick

Tested at factory, hoisted and swung complete circle 1900 lbs. Shipped ready to operate. No wrench or tools required to set derrick on job. Made in two sections. Beam section connects post by tipping in a vertical position and projects at such an angle to clear side wall of building and has sufficient height to hoist wheel-barrows, window frames and timbers. One man can climb a ladder with either section. Consider the durability of a derrick constructed entirely of malleable Iron and Steel and that of Wood, more compact, more powerful.

Derrick complete with three-way block, channel steel brackets, bolts for attaching to building, price $40.00, and four and one-half cents per ft. for crucible steel cable attached. Drum capacity 300 ft.

Special platform and chains for attaching derrick to gondola railroad cars, price $15. Chains for hoisting wheel-barrows, price $2.00.

Three Salary Increases Amount to Over $12,000 a Year

The letters that are here reproduced are only a few of the many thousands of such advancement letters that we have in our files. These men are not men of genius—they are not the sort of men known as "gifted," "naturally bright," etc. They are plain men who have applied themselves diligently to their work and their rise in the world is due solely to spare-time study.

When I enrolled for your Complete Architectural Course I was working as a carpenter for $2.50 a day. A few months later I felt qualified to go into contracting for myself on a small scale. I kept on studying and my business increased. For the last few years, I have been an architect, employing two draftsmen and one stenographer. Last year my income was about $5,800.

EMIL ERICSON,
16 Court Street, Brooklyn, N. Y.

I enrolled for a Course in Architectural Drawing and within a few months was doing actual work drawing plans for buildings. Besides my regular work I have made from $200 to $300 a year extra drawing plans in spare time. I feel very grateful to the I. C. S. for taking me, a carpenter, earning $3 a day, and making an architect of me with the assurance of from $3,000 to $10,000 a year income.

N. R. ADAMS,
Corvallis, Oregon

When I enrolled for the Building Contractors' Course I was working for the Arizona Smelting Company. After studying the Course I went into the general contracting business and have had all the work I can do. All the technical education I have in building I have gotten from the I. C. S. My income will run from $500 to $1,000 a month besides my living expenses.

WILLIAM G. REED,
Twin Falls, Idaho

Would you be willing to give part of your spare time to study that would increase your salary $1,000, $2,000, or $5,000 a year?

If you are not entirely satisfied with your present position mark and mail the attached coupon. Doing so will cost you only postage and will place you under absolutely no obligation; it will bring to you the I. C. S. catalog of Architecture, describing in detail these courses of study that are helping thousands of men to better positions.

Send the Coupon TODAY

International Correspondence Schools
Box 1332, SCRANTON, PA.

Please explain, without further obligation on my part, how I can qualify for a higher salary and advancement to the position, trade, or profession before which I have marked X.

Stanley Tools

"444"

A Combination Dovetail Tongue and Groove Plane

Something entirely new. A Plane that will at one setting cut a dovetail groove, and in the other setting a dovetail tongue to match.

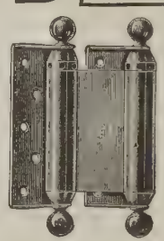
The operation is simple and the accurate and perfect fitting joints obtained, both parallel and tapering, will convince the workman of the utility of this unique and original tool.

A most valuable addition to the kit of pattern makers, cabinet makers, carpenters and wood workers in general.

Send for complete description.

Stanley Rule & Level Co.
New Britain, Conn. U.S.A.

STANDARD THE WORLD OVER.



EVERY TOOL GUARANTEED

DUMB WAITERS

The combination of a pulley, a box, a cord and a bunch of sash weights does not constitute a dumb waiter, but does constitute a first-class man-trap especially effective for maiming women and children. Such combinations were in vogue at the same period as the well-sweep.

Send to the **Sedgwick Machine Works,** 130 Liberty Street, New York, for their Catalogue "K" (which is furnished free on request) and shows a complete line of Dumb Waiters and Hand Power Elevators. Then when an occasion for a dumb waiter comes you will be posted, and if there are any special conditions or requirements they will furnish blue-prints and special information without charge. The Sedgwick Machine Works are the leading specialists in their line, and it will pay any builder to be posted.

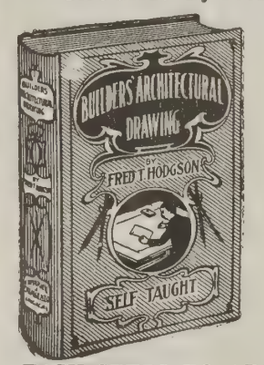
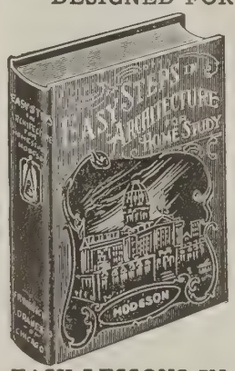
PRACTICAL BOOKS FOR THE BUILDING TRADES



THE STEEL SQUARE—TWO VOLUMES. A PRACTICAL TREATISE ON THE USES OF THE STEEL SQUARE. By Fred T. Hodgson. 600 Pages, 500 Illustrations.

Two Vols., Cloth Binding. Price.....**$2.00**
Single Vols., Part I, Cloth. Price..... **1.00**
Single Vols., Part II, Cloth. Price..... **1.00**

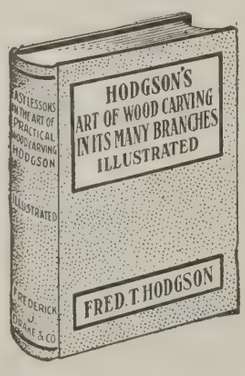
Mr. Hodgson was the first—as well as the last—person who has written on this important tool, and the two volumes now issued contain the earliest and the latest up-to-date methods of applying the STEEL SQUARE for the solution of the many problems this wonderful instrument can solve when in capable hands. The two volumes, named herewith, contain about all that is possible to be done with the square, that is of practical value to the workman, and, as they show nearly all the simple, as well as the difficult things, that can be accomplished with the aid of this tool, there will be little trouble for the workman to work out any minor problem that may confront him, if it is within the purview of the tool. In short, the two volumes contain all that can now, or hereafter, be accomplished with the square. They are profusely illustrated with diagrams, and explanatory sketches, which cover the whole ground of steel square practice. Two volumes of the greatest possible value to the young carpenter.



BUILDERS' ARCHITECTURAL DRAWING SELF-TAUGHT. By Fred T. Hodgson. F. A. I. C. 336 Pages, 250 Illustrations and 18 Folding Plates, 12mo, Cloth Binding. Price.....**$2.00**

This work is especially designed for carpenters and for students of architecture, woodworkers and others who desire to learn drawing at home, and who have not the means, time or opportunity of taking a regular course in school, or college, nor of availing themselves of the offers made by one or other of the "Correspondence Schools."

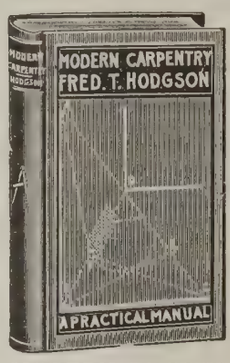
The work commences with a description of drawing instruments and accessories, with rules for using them, and hints as to their care and management. Rules for laying out simple drawings and executing same are given, and the student is taught step by step to draw to scale, first the plans, next the elevations, and finally the details of a cottage, including foundations, walls, doors, windows, stairs and all other items required for finishing a small building complete in every particular.



EASY STEPS TO ARCHITECTURE. PARTICULARLY DESIGNED FOR HOME STUDY. By Fred T. Hodgson, F. A. I. C. 350 Pages, 230 Illustrations, 12mo, Cloth Binding. Price .**$1.50**

As every mechanic employed in the building trades must necessarily have some knowledge of architecture, a book of this kind will be found by him to be a great assistance in acquiring such knowledge without a great expenditure of effort. A part of this work has been for years a sort of text-book in schools where architecture is taught, and is a catechism to some extent. The questions and answers are easily understood and as easily remembered.

The second part of the book deals more particularly with architectural styles, while the first part is mostly devoted to the classic orders, Greek and Roman. Full explanation of the latter styles are made, and illustrations show these styles and give a brief history of their growth and decay.



EASY LESSONS IN THE ART OF PRACTICAL WOOD CARVING. By Fred T. Hodgson, F. A. I. C. 284 Pages, 200 Illustrations, 12mo, Cloth Binding. Price.....**$1.50**

This work, "Easy Lessons in Practical Carving," is prepared in the same happy, easily understood style of writing that has made the name of the author so famous among the working men of English-speaking countries.

The lessons given in this new book begin at the very beginning of carving and lead the young workman by easy steps through the mazes of the art, until he is able to turn out work of a creditable character. The use and care of carvers' tools are given and explained, and the tools described and shown in illustrations, with methods of sharpening and honing the tools, in a clear and interesting manner. All necessary appliances are shown, described, and illustrated, both for holding the work, and for preparing the tools and finishing up the carvings. The various styles of carving are fully explained, such as flat carving, chip carving, incised carving, scratch carving, figure carving, carving in relief, round carving and jewelry carving.

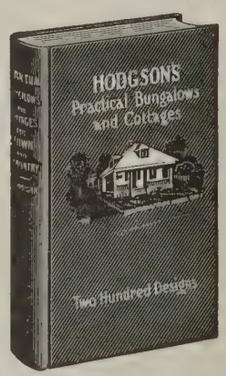
MODERN CARPENTRY AND JOINERY—VOL. I. By Fred T. Hodgson, F. A. I. C. 300 Pages, 318 Illustrations, 12mo, Cloth Binding. Price.....**$1.00**

This is a real modern work, and the large numbers of it that have been sold (over one million) is an evidence that American workmen have found in it the things they expected. It is one of the best books of the kind ever brought out for teaching the young workman the art of correct and easy wood-working. It shows how to lay out roofs, rafters, stairs, hoppers, bevels of all kinds, mitering, coping, circle work, flooring, splayed work, plain stairs and handrailing, cornicing, dove-tailing and many other things the young carpenter will require to know in the performance of his regular work. It is written in a very simple style, and can be understood by any person who can read everyday English. Unlike other works prepared for workmen, it is void of bewildering formulae and algebraic puzzles, and the reader is not asked to wade through long mathematical calculations to get at the kernel of the subject before him. The work contains some 300 illustrations and diagrams, all of which are explanatory and instructive.

MODERN CARPENTRY AND JOINERY—VOL. II. ADVANCED SERIES. By Fred T. Hodgson, F. A. I. C. 400 Pages, 300 Illustrations, 12mo, Cloth Binding. Price.....**$1.00**

This volume is somewhat similar to Vol. I, only on advanced lines, and is intended to follow up the progress made by a study of the first. Indeed, it is simply a continuation of the first volume, on a higher plane, and no workman having mastered the contents of one, will rest satisfied, until he has also mastered the contents of the second volume.

This volume contains some examples of work, with a description of the way the work is performed, and the materials employed. Many very difficult problems are here shown and the solutions and explanations are given and fully explained, many things that at first seem formidable to the unpracticed workman, become quite easy of solution under the magic wand of the author's method of explanation.



COMMON SENSE STAIR BUILDING AND HAND-RAILING. By Fred T. Hodgson, F. A. I. C. 300 Pages, 300 Illustrations, 12mo, Cloth Binding. Price.....**$1.00**

This is an excellent work for the young carpenter who is ambitious of becoming an expert in handrailing and stairbuilding, inasmuch as it commences at the very beginning of the art, and shows how to lay off a stair on the floor, placing the newels, laying off treads and risers, strings, winders, wells and flyers.

The object of the author is to lead the student step by step, in such a way that he takes in the whole art of stairbuilding before he is aware of it. This is decidedly the best and most practical work on stairbuilding in the market, and just what the untrained workman wants. The part of the book devoted to handrailing exhibits three different methods of laying out and working handrails suitable for any kind of stairs, straight, circular, elliptical, or for stairs with landings, doglegged, newels, or cylinders. These systems of handrailing have been taken from the best sources on the subject, and have been revised and edited in the most careful manner.

PRACTICAL BUNGALOWS AND COTTAGES FOR TOWN AND COUNTRY. Arranged and Edited by Fred T. Hodgson, assisted by E. N. Braucher, Architect. 12mo, Cloth, 420 Pages, 400 Illustrations. Price.....**$1.00**

This work contains perspective views and floor plans of over two hundred choice bungalows, cottages, houses and flat buildings, selected with great care to combine architectural beauty, convenience and economy of construction, ranging in prices from $500.00 to $3,800.00. Every plan shown is made by a licensed architect and has been built from, to the entire satisfaction of the builder and within the estimated cost. This work will be found invaluable to the home builder, furnishing many new and up-to-date ideas and suggestions in modern architecture. The number of California bungalows, which the editors have taken great pains to select, are without question the most attractive modern low cost homes ever built. We are prepared to furnish blue prints at a very moderate cost, ranging from $5.00 to $15.00, according to cost of erection, consisting of floor, roof and foundation plans, front, side and rear elevations, with complete type-written specifications.

Any of the above books sent Post or Expressage Prepaid on receipt of price.

LET TRUTH PREVAIL

Do Not Be Disturbed by the Misrepresentations of Competitors on the Asbestos Shingle Patent Situation

Some of our competitors have been grossly misrepresenting, to unfairly influence business, a decision and injunction they obtained from the U. S. Courts, alleged to prevent us from selling asbestos shingles.

We have not considered such business competition as worthy of our notice; but as it has annoyed some of our customers, we laid the facts before the Honorable Court, which has issued the following injunction, and the Court has now enjoined our competitors from continuing such misrepresentations of its decisions.

READ THE LATEST INJUNCTION ISSUED BY THE COURT

THE PRESIDENT OF THE UNITED STATES
to
ASBESTOS SHINGLE SLATE & SHEATHING COMPANY
GREETING:

WHEREAS, it has been represented to us in our Circuit Court of the United States for the Southern District of New York that you, the said Asbestos Shingle Slate & Sheathing Company, have misrepresented to the public the force and effect of a certain interlocutory decree entered by said court on the 16th day of February, 1911, in a certain suit brought by said Asbestos Shingle Slate & Sheathing Company, and Ludwig Hatschek, against the H. W. Johns-Manville Company, and also the force and effect of our writ of injunction issued thereunder on the 18th day of February, 1911.

NOW, THEREFORE, we do strictly command and enjoin you, the said ASBESTOS SHINGLE SLATE & SHEATHING COMPANY, from in any way advertising in words or in substance that this court has held that any cement shingles hitherto made and sold by the defendant, H. W. Johns-Manville Company, infringe on any of the claims of the patent in said suit, or from issuing any circulars or in any other way publishing abroad or saying, or writing this court has held that no cement shingles can be purchased except from the complainant, or that all the claims of the complainant were upheld by the interlocutory decree herein, or in any other way misstating the effect of the said decree, or of publishing the whole or any part thereof or the substance of the same, so that it shall mislead any reader as to its meaning or effect, and

We do further strictly command and enjoin you, the said ASBESTOS SHINGLE SLATE & SHEATHING COMPANY, that whenever you shall advertise the interlocutory decree of this court entered in said suit, or any part thereof, or the substance of the same, in connection with the words "cement shingles," or "asbestos shingles" or the like, that in every such case the said advertisement or circular or other means of publication shall make equally salient to the eye the fact in substance that the said decree of this court forbade the making, vending or using of cement or asbestos shingles or the like, made upon a paper making machine, and that said advertisement shall nowhere contain any statement that the decree of this court forbade the making, vending or using of any cement or asbestos shingles unless such statement be accompanied as aforesaid with the statement in substance that the said shingles so forbidden are those made upon a paper making machine.

WITNESS THE HONORABLE EDWARD D. WHITE, Chief Justice of the Supreme Court of the United States, at the City of New York, on the 1st day of June, 1911, and in the hundred and thirty-fifth year of the Independence of the United States.

JOHN A. SHIELDS, Clerk of the Circuit Court.

We have been and are selling shingles which do not infringe our competitors' patents, because they are made by a new and better process, covered by letters patent which we control.

J-M Transite Asbestos Shingles Are Not Made Like Paper on a Paper-Making Machine. They Are Moulded Solid and Compact and are Far Superior to the Laminated Kind.

Be the Man Who Gives Orders

Don't forever be at the beck and call of some petty, tyrannical "boss." It is every American's right to be independent. Your "boss" of this year may be your subordinate of next if you make the effort to better your position. But you must have special and individual preparation to rise above the rank and file. We offer you an opportunity to become **the man who gives orders.** To carpenters, bricklayers, and all men in building trades, we offer a short but complete course in DRAFTING.

Estimating, Plan Reading, etc.

BY MAIL

You know the advantages of being able to read plans and to estimate, and the opportunities for promotion and prosperity that come to those with that ability. We can positively teach you, with our simply written, practical lessons. Hundreds of plans of buildings, in course of construction in Chicago, are studied from.

If you are a bricklayer, mason, carpenter or builder, you need this course—it will bring you higher wages. If you are a foreman or superintendent, you need this course—it will enable you to become a successful contractor. If you are a contractor, you need this course—it will help you to figure closer. It will eliminate mistakes and increase your profits.

The lessons are approved by experienced Chicago architects. We have partial courses to fit your individual need, if you have had previous experience. Start now on your journey to success. Don't say you can't do it—you can; don't say you haven't the time—take it; don't say you haven't the money—earn it as you study. Determine now whether you will advance in salary and position or let other men go ahead of you. Send for free folder, now.

THE HARDWOOD FINISHER

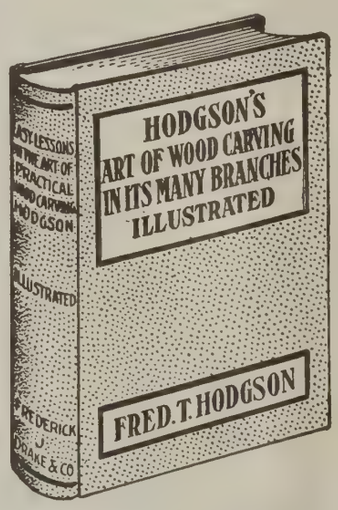
BY

FRED T. HODGSON

1906 EDITION

In Two Parts

PART ONE, giving rules and methods for working hardwoods, with description of tools required, the methods of using, and how to sharpen and care for them, including saws, planes, files, scrapers, chisels, gauges and other wood-working tools. How to choose hardwoods for various purposes, and how to work and properly manage veneers. The proper use of glue, directions for preparing glue, blind or secret nailing, how done and how finished. How to sharpen and use scrapers of various forms, with illustrations showing the tools and how to handle them properly, etc



PART TWO treats on filling, staining, varnishing, polishing, gilding and enameling woodwork of all kinds of woods.

It also treats on renovating old work, repolishing, revarnishing and wood finishing generally. There is a short treatise on dyeing woods in various colors for inlaying and marquetry work, with rules for making staining, dyes, fillers and polishes of various kinds, French polishing, hard-oil finish, rubbed and flat finish, treatment of hardwood floors, waxing, polishing, shellacking and general finishing of hardwood in all conditions.

New Books for Building Mechanics

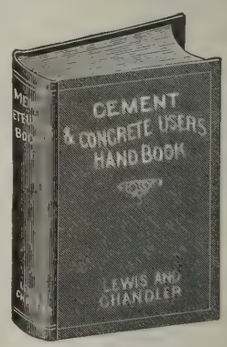
MODERN PLUMBING ILLUSTRATED. By R. M. Starbuck.

This book represents the highest standard of plumbing work. It has been adopted and used as a reference book by the United States Government, in its sanitary work in Cuba, Porto Rico and the Philippines, and by the principal Boards of Health of the United States and Canada.
It gives connections, sizes and working data for all fixtures and groups of fixtures. It is helpful in demonstrating and in figuring work. It gives the mechanic quick and easy access to the best modern plumbing practice. Suggestions for estimating plumbing construction are contained in its pages. This book represents, in a word, the latest and best up-to-date practice, and should be in the hands of every architect, sanitary engineer and plumber who wishes to keep himself up to the minute on this important feature of construction. 400 octavo pages, fully illustrated by 55 full page engravings. Price.....**$4.00**

STANDARD PRACTICAL PLUMBING. By R. M. Starbuck.

A complete practical treatise of 450 pages covering the subject of Modern Plumbing in all its Branches, a large amount of space being devoted to a very complete and practical treatment of the subject of Hot Water Supply and Circulation and Range Boiler Work. Its thirty chapters include about every phase of the subject one can think of, making it an indispensable work. Fully illustrated by 347 engravings. Price.....**$3.00**

PRACTICAL STEAM, HOT-WATER HEATING AND VENTILATION. By A. G. King.



This book is the standard and latest work published on the subject and has been prepared for the use of all engaged in the business of steam, hot water heating, and ventilation. It is an original and exhaustive work. Tells how to get heating contracts, how to install heating and ventilating apparatus, the best business methods to be used, with "Tricks of the Trade" for shop use. Rules and data for estimating radiation and cost and such tables and information as make it an indispensable work for everyone interested in steam, hot water heating and ventilation. It describes all the principal systems of steam, hot water, vacuum, vapor, and vacuum-vapor heating, together with the new accelerated systems of hot water circulation, including chapters on up-to-date methods of ventilation and the fan or blower system of heating and ventilation. 367 pages. 300 detailed engravings. Price.....**$3.00**

CONCRETE CHIMNEYS, SLATE AND ROOF TILES. By A. A. Houghton

The manufacture of all types of concrete slate and roof tile is fully treated. Valuable data on all forms of reinforced concrete roofs are contained within its pages. The construction of concrete chimneys by block or monolithic systems of is fully illustrated and described. A number of ornamental designs of chimney construction with molds are shown in this valuable treatise.....**50 Cents**

POPULAR HANDBOOK FOR CEMENT and CONCRETE USERS. By Myron H. Lewis

This is a concise treatise of the principles and methods employed in the manufacture and use of cement in all classes of modern works. The author has brought together in this work, all the salient matter of interest to the user of concrete and its many diversified products. The matter is presented in logical and systematic order, clearly written, fully illustrated and and free from involved mathematics. Everything of value to the concrete user is given, including kinds of cement employed in construction, concrete architecture, inspection and testing, waterproofing, coloring and painting, rules, tables, working and cost data. Price.....**$2.50**

ORNAMENTAL CONCRETE WITHOUT MOLDS. By A. A. Houghton.

The process for making ornamental concrete without molds, has long been held as a secret and now, for the first time, this process is given to the public. The book reveals the secret and is the only book published which explains a simple, practical method whereby the concrete worker is enabled by employing wood and metal templates of different designs, to mold or model in concrete any Cornice, Archivolt, Column, Pedestal, Base Cap, Urn or Pier in a monolithic form—right upon the job. These may be molded in units or blocks, and then built up to suit the specifications demanded. This work is fully illustrated with detailed engravings Price.....**$2.00**

CONCRETE FROM SAND MOLDS. By A. A. Houghton.

A practical work treating on a process, which has heretofore been held as a trade secret by the few who possessed it, and which will successfully mold every and any class of ornamental concrete work. The process of molding concrete with sand molds is of the utmost practical value, possessing the manifold advantages of a low cost of molds, the ease and rapidity of operation, perfect details to all ornamental designs, density and increased strength of the concrete, perfect curing of the work without attention and the easy removal of the molds, regardless of any undercutting the design may have. 192 pages. Fully illustrated. Price.....**$2.00**

CONCRETE WALL FORMS. By A. A. Houghton.

A new automatic wall clamp is illustrated with working drawings. Other types of wall forms, clamps, separators, etc., are also illustrated and explained.....**50 Cents**

CONCRETE FLOORS AND SIDEWALKS. By A. A. Houghton.

The molds for molding squares, hexagonal and many other styles of mosaic floor and sidewalk blocks, are fully illustrated and explained.....**50 Cents**

CONCRETE SILOS. By A. A Houghton.

Complete working drawings and specifications are given for several styles of concrete silos, with illustrations for molds for monolithic and block silos. The tables, data and information presented in this book are of the utmost value in planning and constructing all forms of concrete silos....**50 Cents**

MOLDING AND CURING ORNAMENTAL CONCRETE. By A. A. Houghton.

The proper proportions of cement and aggregates for various finishes, also the methods of thoroughly mixing and placing in the molds, are fully treated. An exhaustive treatise on this subject that every concrete worker will find of daily use and value.....**50 Cents**

Any of these books sent prepaid on receipt of the price. Address **NATIONAL BUILDER, Pontiac Building, CHICAGO, ILLINOIS**

RED GUM

The New Open-Air Stairway Tenements in New York

HENRY ATTERBURY SMITH, *Architect* WILLIAM P. MILLER, *Associate Architect*

THIS GREAT GROUP OF BUILDINGS IS THOROUGHLY UP-TO-DATE. THESE BUILDINGS ARE BUILT WITH

RED GUM TRIM THROUGHOUT

Builders all over the United States are becoming aware of the superb utility, great *beauty* and *extraordinary economy* of RED GUM (when it is properly selected and intelligently manufactured.) Watch that last point. Buy it *only* of *responsible* manufacturers, who *care what happens to it AFTER YOU BUY IT AND INSTALL IT.*

SAP GUM

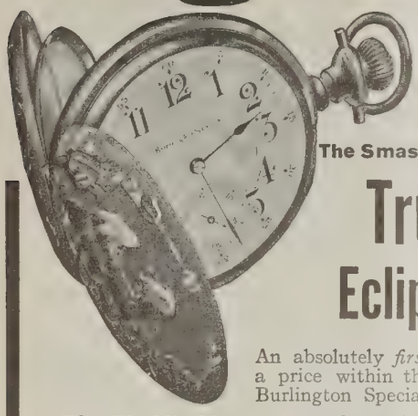
Then there's SAP GUM—from the same tree.

There is no part of a frame house where SAP GUM may not be satisfactorily used instead of any one of a dozen higher-priced woods.

A number of progressive GUM manufacturers have demonstrated that PROPERLY SEASONED and INTELLIGENTLY HANDLED GUM DOES NOT WARP OR TWIST.

SAP GUM makes the best Siding on Earth for the Money.

It takes TIME to season GUM properly. A small producer cannot afford to wait.



The builder wants RELIABLE GUM, and his safety accordingly lies in specifying only the product of some producer of RECOGNIZED STANDING and ADEQUATE RESOURCES.

Builders desiring to see samples of ***RED GUM*** *and* ***SAP GUM*** *both rough and finished, or who wish market prices of selected* ***RED GUM*** *and* ***SAP GUM,*** *are invited to correspond with any of the following firms:*

Fighting The Trust!

The Smashing Anti-Trust Fight Now On!

Trust Prices Eclipsed at Last!

An absolutely *first-class* **high-grade** watch at a price within the reach of the people — the Burlington Special Anti-Trust Watch.

The World's Masterpiece of watch manufacture—the Burlington Special—now sold direct to the public at its *rock bottom, anti-trust* price and besides without middlemen's profits.

We do not care what it costs

—we will uphold our independent line and so we are making the most sweeping, baffling offer ever made on watches.

Some trusts are legal and some are not. **We do not say that the watch trust is illegal;** but we do say that the **methods** of the giant factories in making "contracts" with dealers **to uphold double prices** on watches is very **unfair**—unfair to **us** and **you.** Hence our **direct** offer on the Burlington at the **very same** price the **Wholesale** Jeweler must pay.

This is *your* opportunity—**NOW**—while this great Anti-trust offer lasts—get the best watch made anywhere at one-third the price of other high-grade watches. Furthermore, in order to fight the Trust most effectually, we even allow terms of

$2.50 a month

on our finest watch—easiest possible payments at the rock-bottom price, the identical price the **Wholesale** Jeweler must pay.

WATCH BOOK ON REQUEST.

Now do not miss this opportunity. At least we want you to know about WATCHES and WATCH PRICES. Write to-day.

BE POSTED—Send a postal or letter and get the free book. It tells you how to judge a watch. You should get this great book if you ever expect to own a watch.

BURLINGTON WATCH CO.
Dept. 6973 **19th and Marshall Blvd., CHICAGO**

BE YOUR OWN ARCHITECT

Learn How by Studying the Best Designs by the Best Architects

The ambitious builder has now an opportunity to obtain designs for buildings of all kinds that will give the best ideas for his own designing, and something to interest those for whom he is to build.

These designs were selected from the best modern work of the best architects in all places, and so represent buildings appropriate for the North, East, South and West. Houses, schools, churches, libraries, stables, etc., are included.

These studies were published in parts, each of which contains at least twenty full-page plates of these splendid designs beautifully printed.

These parts were published at $1 each; but while the supply lasts, the price of a part has been reduced to 25 cents. Any number of parts can be bought. A trial order of four parts for $1 will give you a good start.

LESSON No. 1

Lost Profits

The Rainy Day for the Contractor

HAVE YOU THOUGHT

About the Many Floors
in the homes and buildings you know of that are rough and unsightly—paint stained and spotted—or new floors that have worked out of shape in the seasoning process?

That With a Machine
you can send a man around on rainy days or at odd times and **finish** (that is, scrape and sandpaper perfectly) 200 square feet of new floors or about half that much of old floors per hour.

That This Is
not only a rainy-day job, but could be made a permanent business—paying handsome profits—from $15 to $30 per day.

That there is only one machine
that will do this—with one-third the work, worry and expense, of the others—that is—

The Triple "A" Spring Driven Floor Smoother

Now we have a folder for you, telling you how to do this work properly and artistically, and the prices that should be charged, and showing you many lost profits; and maybe some other things you've not thought of.

And that we send you a machine to do your first job with, and if from any cause it does not look to be a paying proposition or you see that you have no need for it—send it back without one cent of expense—we'll even return your stamp. Now, write us to-day

About the Triple "A"

Weight for scraping old floors and roughing, 150 lbs. are available. For scraping new floors or smoothing the machine is generally used with 130 pounds. Weights are slotted so that any desired pressure can be brought to bear over the scraper.

Power—Using the Triple "A" Motor Spring on a floor scraper is like two men working on a long crosscut saw. The spring more than doubles the working capacity of the machine and is an absolute necessity in doing heavy cutting.

Adjustability The scraper blade is held in an adjustable clamp—no wrench is required to fasten it and the blades are whole and free from slots. The scraper clamp can be adjusted to opposite shear-cutting angles so that the floor can be roughed at one angle and smoothed at the other. It can be further swung up or down to fit the angle of any scraper edge.

The Handle can be adjusted to suit any height and telescoped for use in small rooms.

A Special Tool Box is furnished with each machine containing three different thicknesses of knives—these knives are double edged and of different radius, furnishing a variety of twelve different cutting edges. A file, oil stone, can of oil, burnisher, wrench and some white cotton waste are also included in the tool box.

An Automatic Sandpapering Attachment completes the Triple "A" Floor Smoothing Outfit. With this you are fully equipped to do any job of floor surfacing that may offer.

Genasco

the Trinidad-Lake-Asphalt Roofing

Consider Genasco from the three vital standpoints:

1. **What it *does***
2. **What it *costs***
3. **What it *saves***

1. Genasco waterproofs your roof to last. Trinidad Lake Asphalt, used in making Genasco, is Nature's everlasting waterproofer that has resisted the influences of weather-changes for centuries. It carries into Genasco these same weather-resisting qualities, and makes it defy rain, snow, wind, sun, cold, and heat; and it makes it *permanently* waterproof.

2. Genasco costs about the same in the beginning as the so-called "asphalt composition" or the "special process" roofings which would be wonderfully good imitations of Genasco if they didn't crack, break, and go to pieces. But they can't stand the real test—the weather. They haven't the lasting life which *natural* asphalt gives.

Genasco is economical because it resists and lasts.

3. The saving in Genasco Roofing is plain. You do away with leaky roofs and the expense of repairing them; you prevent costly damage to rooms and furniture, and you save the cost of re-roofing. Genasco first-cost is last-cost.

Get Genasco Roofing—either mineral or smooth surface. Guaranteed, of course.

The Kant-leak Kleet for roofing seams prevents nail-leaks, does away with dauby cement, and gives a fine finish to the roof.

Ask your dealer for Genasco with Kant-leak Kleets packed in the roll. Write us for samples and the Good Roof Guide Book.

What if an Akron Should Fall?

—no harm done. Why? Because it's a "battleship" level—built to withstand tough tumbles. No thin, brittle, spirit-tube in an Akron. It's double: (1) the inner tube is similar to the ordinary level; (2) for additional safety this is protected—made doubly strong—by an outer tubing of heavy clear gauge-glass with elastic rubber bearings between the two tubes. (See cut)

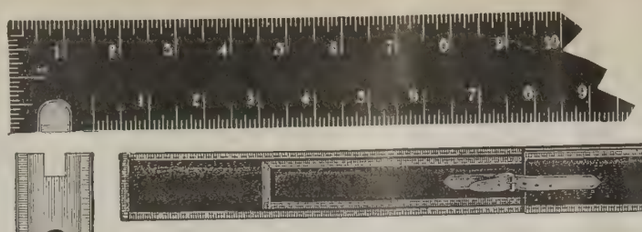
That's why

Akron Eclipse Levels

stand the racket; that's why carpenters, masons, all classes of workmen may rest easy when they own an Akron.

Besides its strength—it is convenient to handle, well balanced and has the exclusive

Easy Reading Feature



The two fine silver lines (see cut) encircling spirit tube—one at either end of bubble—show instantly "L-E-V-E-L." It's a scientific, high grade, dependable instrument. The Akron is made in 33 styles. In spite of its high grade construction and careful testing before leaving factory it costs no more than the ordinary level. Sold by hardware dealers and instrument-men everywhere. Catalog free. Write today for it.

NICHOLLS NEW TAKE-DOWN SQUARE

Has a Joint so Constructed that It Couldn't Get Out of True if It Wanted To

Guaranteed Accurate and to Remain So

The main feature of our new Take-Down Square is that it will always stay true. It is so constructed that the tongue is held down into beveled bearings by a spring, and these bearings are made so as to take up the constant wear which comes in taking square apart and putting it together, thereby producing constant accuracy. Rust-proof canvas case with each square.

OUR NEW LOCKING DEVICE securely Locks Tongue to Body and prevents Tongue from slipping out.

Does not lock with a key such as other makes of Take-down Squares, but, is simply operated with the thumb.

No running to your Tool Box for a key, or "I forgot the key and left it home." NO KEY TO LOSE. ALWAYS READY. ALWAYS ACCURATE.

If your dealer does not handle our tools and will not order them for you, write us. We have something to offer.

We prepay express if ordered direct.

Information on Concrete

Every Architect, Contractor and Builder should have a copy of

Concrete and Reinforced Concrete Construction

By HOMER A. REID

200 working drawings of bridges, bridge piers and culverts; 60 working drawings of sewers, water mains and reservoirs; 30 working drawings each of retaining walls and dams; 200 working drawings of buildings and foundations, including shops, roundhouses, etc. Every structure illustrated is described, the method of construction is explained and where possible the cost is given. There are chapters telling **how to compute girders, arches, columns, tanks, bins, walls, conduits and chapters on proportioning, mixing and laying concrete,** on **doing concrete work in freezing weather,** on **facing and finishing concrete,** on **waterproofing concrete,** on the **physical properties of concrete,** on **cement testing** and on **concrete block manufacture and construction.**

This book contains more text pages, more drawings and **more tables of test data on concrete and reinforced concrete construction than any other book in the world. It has more new matter**—material never previously published. This work is a combination of several books in one; **it is complete, up-to-date and original. No other book on concrete contains one-tenth as much of the very latest data on tests, theory, and practice.** The cost to publish this book has been more than double the original estimate, but the price will for the present remain at $5 net postpaid. THE WINTHROP

SOLID TAPERED ASPHALT SHINGLES

Are of a Cool, Gray Slate Color

And have the durability of asphalt—the fine appearance of slate and the light weight and low cost of wood shingles. They are fire-resisting—weather proof—wind and sun-proof and never crack, break or fall off. Laid with regular shingle nails, the same as wood shingles.

Special Inducements to Those Who Apply First Roof in Each Town. Catalogue on Request

WINTHROP ASPHALT SHINGLE CO., 1100 THE TEMPLE CHICAGO, ILL.

YOU CAN SAFELY RECOMMEND

Compo-Board

It makes the best walls and ceilings. Dry, warm, fire-resisting and moisture proof.

Compo-Board walls will outlast lath and plaster; will not crack, crumble or fall off. Can be easily put on without waste of time waiting for plaster to dry.

They always look well. No ugly blotches where moisture has gathered. No unsightly scars where the walls have been patched. Will take paint, paper or kalsomine perfectly.

In addition to being a perfect wall lining, Compo-Board can be used as a back plaster for partitions, for lining summer cottages, barns and poultry houses. It has many uses around the house and in the office and factory.

Compo-Board is made of strips of thoroughly dried lumber matched together and well glued. These strips are then covered with a specially prepared moisture proof paper, which is cemented under intense heat heavy pressure. This makes a wall lining that will last indefinitely.

Can be had in strips four feet wide and one to eighteen feet long, any length you want in even feet.

JOHN HARDIN & CO.

Established 1876

4541-4549 Cottage Grove Avenue

CHICAGO

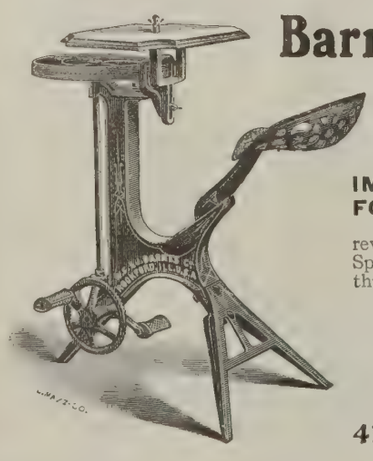
MASTER BRACE

The general appearance of this Brace rejoices the lover of fine tools. The metal parts are handsomely nickeled and the head and handle are of highly finished cocobolo. Both head and sweep-handle are ball-bearing, reducing all friction to a minimum.

All ratchet parts are covered and in that way protected from dust. The ratchet teeth cut directly upon the base of the tail socket, in a manner least likely to get out of order.

It is impossible for the chuck to work loose, whether the ratchet is worked left or right, because of the manner in which it is attached to the sweep by a flat-head machine screw and a patent washer, which is in the shape of a shallow cup.

It is in the chuck, the most vital part of any bit brace, that Millers Falls skill in brace-making has culminated. The sleeve is of a new pattern, just fitting the hand, and is reinforced at the lip to meet the strain at that point. The tail socket is made from solid bar steel, unbreakable under the severest usage. The jaws are so hinged upon a spring as to transmit any strain to the stout sleeve.



The jaws open parallel and close to conform to the shape of the bit used. Three grooves cut lengthwise in each jaw, making eight points of contact, insure the tenacity of grip.

The Master Brace is made in 4 sizes, with 8, 10, 12 and 14 inch sweep.

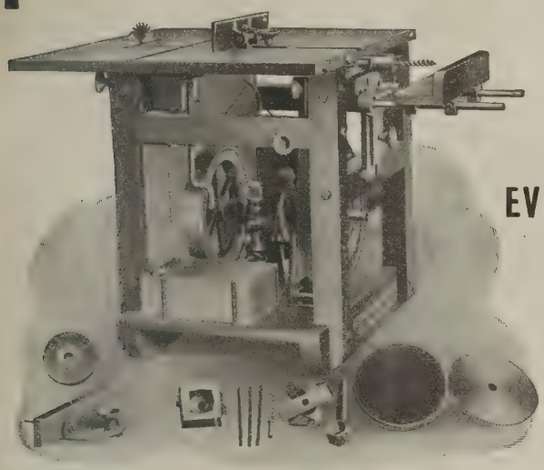
GREYHOUND HAND SAWS

SPEED & EASE
TRADE MARK.

The more you know about hand saws the more you can appreciate "GREYHOUND" hand-made hand saws, with their easy-running and rapid cutting qualities and wonderful durability. This saw will be imitated by others—but not equalled.

They are made from Bishop's Refined "GREYHOUND" Steel—a material which leads everything yet produced for use in hand saws. The purity of the steel, the toughness, the even and accurate temper, gives a saw that is the most suitable for particular work, and the most practical for ALL work where a hand saw is used. Made in both straight and skewback, also narrow patterns. Specify which you desire. Remember our warranty accompanies each saw. And the warranty means that if 30 days' trial does not convince you that the "GREYHOUND" saw is the best for your use, you get your money back.



Order one today and let us take all the risk. If you want literature first, write us.

Worst and Shepardson, Architects, Aurora, Ill.

For Floor Plans, Elevations and Details, See Supplement Sheet of this number. Estimated Cost, $3,183.24

THE AURORA HOUSE

ON THIS page we show a typical suburban house of moderate cost. The architects have, by using wide siding and designing a unique construction of the porch, given an interesting appearance to what otherwise was a rather plain, square building. The interior has proved to be as convenient as the exterior is attractive. It might be noted that the house was built, including architect's fees, for slightly under the estimated price given here.

Dormer work	10.00
144 ft. cornice work, 10c	14.40
Porch work	20.00
Finishing cellar frames	10.00
Coal bin	4.00
Finishing front door	4.50
Finishing rear door	3.50
Finishing side door	4.00
Finishing double-acting door	4.00
Finishing 2 cased openings, $2.00	4.00
Finishing 10 inside doors, $3.00	30.00
Finishing 21 windows, $2.00	42.00
Finishing 450 ft. inside base, 6c	27.00
Finishing 300 ft. picture mold, 1½c	4.50
Putting up front stairs	25.00
Putting up cellar stairs	6.00
Outside steps	5.00
1,650 ft. finish floor, $20	33.00
Smoothing, $15	24.75
Closet and pantry work	20.00
Incidentals, 10%	48.93
Total carpenter labor	$538.29

RECAPITULATION.

Excavating and masonry	$514.00
Lumber bill	685.22
Mill work	425.75
Carpenter labor	538.29
Plastering, 580 yards, 28c	162.40
Electric wiring	50.00
Plumbing	260.00
Hardware and nails	46.00
Tinwork	35.00
Painting	180.00
Furnace	135.00
Incidentals, 5%	151.58
Total estimate	$3,183.24

The approximate cubic feet contained within this building is 18,480, from bottom of cellar, making the cost per cubic foot very nearly 10¾ cents.

EDITORIAL NOTES AND COMMENTS

Now is the time to overhaul storm doors and see that all are in readiness for putting in place for the coming winter.

* * *

If there is to be any repairs made on your plumbing plant, now is your time to have it attended to, as plumbing repairs after frost and snow arrive, are always very inconvenient, and often much more expensive than when the weather is warm.

* * *

Furnaces, heaters, radiators, grates and other similar appliances, should be examined and repaired if necessary now, and plumbers whose duty it is to attend to these matters, should not "put off" the work until cold or damp weather demands their use. It often transpires that when the services of these appliances are suddenly called upon, serious and imperative repairs are found necessary, which may require considerable time to adjust. This delay may, and does, in some cases, result in very disagreeable consequences to the inhabitants of the house, particularly when there are young children or delicate women living there, as colds, catarrh and even more serious trouble may follow.

* * *

Some days ago, a scaffold on which a painter and his apprentice boy were re-varnishing a store window framework, gave way, and the two men were precipitated to the sidewalk on an iron grating. As the distance from the scaffold plank from which they were working was not more than six feet from the plank, the men were not seriously hurt, and were able to walk to a hospital—which was not far away—for repairs, though the boy stands a good chance of being disfigured for life, he having a deep gash just under his right eye. An examination of the scaffold revealed the fact that one of the brackets on which the ends of the plank platform rested, was not fastened to the window but was supported by a loose piece of inch board cut in from the sill to the underside of the bracket, and which, by the movement of the workers, fell out, and the arm of the bracket was wrenched off, causing the men and plank to fall.

* * *

This incident—it can scarcely be called an accident—caused a number of people to gather about the scene, and quite a variety of remarks, criticisms and suggestions were made by the bystanders, and we give a few of them: "Workmen in this country take too many chances," said one man who seemed to know what he was talking about, "and something ought to be done to prevent every Tom, Dick and Harry, from building scaffolds, unless they have some knowledge of the art, and of the strength of materials. Most workmen," he continued, "do not seem to care whether they work on one nail or on six, and it is often impossible for a foreman or other person in authority, to know if a scaffold is sufficiently strong or not, and it's up to the workmen to look out for his own safety, which he often fails to do. Men take too many risks."

* * *

Another bystander remarked "That steps should be taken in every state and municipality to bring about such legislation to prevent the great loss of life that results through improper scaffolding, and men should be warned and told that all scaffolds are more or less dangerous. Every day I see men at work on weak boards and improperly constructed scaffolds, and I have often warned them as to the dangerous condition of their boards and planks, but in most cases, my good intentions have either been sneered at, or I have been jibed and looked upon as a meddler and told to mind my own business. Often men are rushed and efforts are made to make one man do two men's work, and no time is given to examine the scaffolds on which they are to risk their lives. In many cases the scaffolding is the biggest part of the job, and it often takes more time to build or suspend the scaffold than it does to do what is required to be done, and so things may be done in a slipshod manner. The experienced men are not likely to meet with accident, however, but the greenhorns need to be watched."

* * *

Contractors, when making an estimate, rarely provide a sum for building scaffolds. Sometimes they do set off a percentage for material, leaving out cost of construction, and because of this the structures are often flimsy and slovenly built. In consequence, thousands of lives have been taken because of the parsimony of some owner or contractor, who, innocently or otherwise, thought only of profits, even though loss of life was the result of such false and mistaken economy. The greatest care should be taken when erecting scaffolds, and good, strong materials should in all cases be employed, and any lumber or timber that show signs of rot, dose, brashiness, shakes, knots or other imperfections, should not be used on the works. Poles and putlogs that have been used as scaffolding on brick buildings should undergo a strict examination before being used. Many poles have been used dozens of times, and in taking down and moving from one place to another, they sometimes get broken or cracked, or otherwise injured to such an extent that their use would be dangerous. Putlogs, being short, are not so apt to be injured in moving, still an inspection of them is quite necessary, as generally in brickwork, they are required to carry big loads of brick, mortar and men. Other things to be considered, are the ropes employed for lashing the putlogs to the scaffolding poles. These become worn, untwisted, and rotted to such an extent as to be unable to bear the strain they may be required to carry. We have often seen a thousand or more of bricks piled on a pole scaffold, along with a ton or more of mortar, and from four to eight men. Imagine a scaffolding, two or three stories high, giving way with all this weight, and the men on it being precipitated to the ground. The result would be bruises, wounds, broken limbs, and, very likely, deaths. It seems scarcely credible, but we are told by certain statisticians that more deaths result from defective scaffolds and carelessness while making use of them, than from railway collisions and wrecks. A man falls from a scaffold and is killed; two or three lines in the news columns of a local paper simply announces the fact, and that ends it. And this is happening every day, but a railway collision or wreck, when ten to fifteen persons are killed, is heralded all over the country by the newspapers in large print and a column in length. This looks terrible, and is terrible, but it is hardly worse than having the same number killed in as many different places by the falling of defective scaffolding—which might have been avoided, if careful and diligent attention had been exercised.

Our attention has more than once been called to the question of swinging doors, which seem to be too common in many places, and when opening outward onto a street, and pushed vigorously from the inside, constitute a dangerous menance to pedestrians passing at the time. A case in point happened a few days ago, in a well known hotel, where an elderly lady was passing one of these doors. A messenger boy or waiter, engaged in carrying a meal on a tray, both his hands being engaged, gave the swinging doors a vigorous kick from his side, and as was to be expected, the door flew open at high speed. The lady, who was carrying a small parcel in one hand and leading a little girl with the other, was utterly unable to protect herself when thus unexpectedly assailed, and received quite a severe blow, the force of which was fortunately broken somewhat by the parcel she was carrying. Had she, however, been walking but a few inches nearer the wall, she would undoubtedly have suffered quite a serious shock, if not injury. This is one of the many cases that happen from time to time where doors are made to swing both ways, as young people never consider that some person may be just at the door and about to pass out, and trouble follows. As a rule, swinging doors are neither safe or convenient and should not be tolerated in any position. Doors should not be allowed to open outwardly on any thoroughfare, only in such places as may be used for public purposes, such as halls, rinks, churches and other public buildings of a similar kind, all of which is provided for by legislation. In hotels, shops, and similar buildings, the revolving door may be used, but even these have their limitation, and it is easy to imagine cases where the revolving door would prove inefficient, but, for general use where no exceptional cases would arise, there is no substitute in sight.

* * *

Exploration in the ancient city of Babylon is proceeding and the last report of the German Oriental Society gives interesting particulars of it. The palace of Nebuchadnezzar is being laid bare in all its vastness, and the line of fortification of the heights on which the palace stood is now almost completely traced.

The streets and private dwellings lying round the foot of the hill are being cleared. Among other finds is a small temple, the work of Nebuchadnezzar, beautifully built, in apparently perfect preservation and still showing the black and white color scheme characteristic of the Assyrians.

CALIFORNIA'S MODERN MISSION BUILDINGS

By HORACE F. STOLL (Continued from September.)

WITHOUT a doubt the most pretentious mission building in San Francisco is the new Alcazar Theater—a class A structure, dignified in appearance and beautifully proportioned. The red-tiled towers set off the front of the theater to advantage and the massive cream walls suggest solidity and stability. Nothing but steel and concrete were used in its construction, so theater-goers are assured safety in case of fire or earthquake during a performance.

ARCH AT LODI, CAL.

The mission style is not suited to tall buildings, and so you see none of this type in the new down-town business section. The modern office structure demands well-lighted rooms and plenty of them. In the mission days, on the other hand, there was little need of windows, since a dim light was more in keeping with the solemn atmosphere of the simple houses of worship. The moment you puncture the walls of a mission building with too many openings, you lose the effect of massiveness and strength, two qualities that give them their distinctive appearance. Heavy walls were a necessity before the Gringoes came, a precaution against earthquakes and the ravages of time, and a protection in case of Indian uprisings or raids from the pirates who cruised in the South Seas in quest of booty and on several occasions sacked the churches and carried off their valuables.

Another example of how attractively the ideas of the padres may be utilized in a modern building is the series of five mission flats that ramble up the side of a hill on Sacramento street. They are unique indeed and represent an outlay of $30,000. The lot is 56 by 104 feet. However, the building is so arranged about a terraced court that from across the street, the lot presents the appearance of being at least twenty feet wider than it really is. The exterior walls are finished in klinker brick and cement, with redwood beams and cornices left natural. The irregular roof is of bright red tile.

THE PUTNAM HOME, ALAMEDA, CAL.

The largest flat, occupied by the owner, who is also the architect, contains 14 rooms. The others have 9, 8, 6 and 5 rooms, respectively. Each flat has its separate mission entrance handled in an individual manner. Heavy oak doors, ornamented with immense iron hinges, locks and knockers, open into the reception halls and living rooms, with large inglenook fireplaces and high backs built in. The ceilings are heavily beamed and the woodwork is beautifully stained a rich, dark brown. Not a bit of moulding is used in the entire building and the millwork was all made on a circular saw, and left perfectly square and plain.

The most typical room in the flats—in fact, the only one in which any real attempt has been made to carry out the mission idea in the interior—is the architect's den or library. It is diagonally beamed and contains a big open cobblestone fireplace that would prove a delight to any man who enjoys a cosy lounging place where he can toast his feet in luxurious ease, or read to the rhythm of the crackling fire. Bookcases and seats are built in the wall and four mission bell chandeliers, especially designed, shed a soft radiance at night. Heavy mission furniture, which is usually better suited to halls or clubrooms, is distributed about the room. The long straight lines and the rich leather upholstery add not a little to the "atmosphere" of the den.

In planning the arrangement of his flats, the architect constantly kept in mind the necessity of plenty of light and sunshine in every room. The outlook from the windows overlooking the court is dazzling on a sunshiny day, for the cream plastered walls reflect the sunlight wonderfully.

The court is charming. It is laid out in terraces, the first being a flat lawn, dotted along the edge with klinker brick pots holding palms. The second is a sloping lawn running up to a cement wall that is draped in nasturtium vines, while the third is a circular center garden filled with flaming red geraniums. Formal looking bay trees, palms in terra cotta pots and an abundance of flower boxes overflowing with red geraniums and trailing

MISSION DOLORES, SAN FRANCISCO.

vines complete the floral decorations. The walks are paved in large square tiles of a rich dark brown.

An architectural mission gem on a smaller scale is the $15,000 cottage of Kingman B. Putman in Alameda, across the bay. It is in a setting of native oaks and rare plants and shrubs, the lot occupying a quarter of a block. The outside walls are of concrete plaster with a red tiled roof and an immense arcade mission porch of cement inlaid with red brick. The windows are small, with long narrow panels of plate glass. No attempt was made to follow out the mission idea in the interior. The large living room and dining room are finished in South American oak. The walls are paneled and covered, between the panels, with Japanese art tapestry. The ceilings are beamed with large heavy beams running the length of the rooms and smaller ones running across. The ceilings are also covered between with Japanese tapestry. The floors of these two rooms are highly polished maple stained to harmonize with the walls and are connected by immense oak doors. Each room has a large mission fireplace, made of tile and solid oak. The dining room is ornamented with a handsome sideboard built in the wall and the living room has wide seats and book shelves on each side of the fireplace. The sleeping rooms are finished in hard woods and the bathrooms with mosaic floors and high tiled walls.

There are mission bath houses, casinos, boat houses, even stables, that might be mentioned, but we cannot overlook the new

mission churches which have sprung up in many of the cities that were not favored by the padres. St. Mark's Protestant Episcopal Church in Berkeley is one that has all the charm of the old adobe missions. It is located at the intersection of two of the college city's most beautiful streets, both shaded with trees, and is accessible from all parts of the town.

The approach from the vestry room to the rear of the seats, which is used each Sunday by the processional choir, is an arched corridor of truest mission design protected by a sloping roof of red tiling. The towers, two in number, also carry out the designs

MISSION CAMPANILE, MILLS COLLEGE.

of old Spanish cathedrals and present a most imposing appearance. The church seats seven hundred and fifty persons and cost in the neighborhood of $30,000. The interior decorations carry out the general scheme of the builders, making St. Marks one of the most representative mission churches, planned by the modern school of architects.

As we came out of the pretty little church, with its old-world atmosphere, I could not help contrasting the rapidity and ease with which our new mission buildings are erected in comparison with the slow, tedious process of the olden days. The more important of the California missions were built of stone and a hard burnt brick that will even now turn the edge of the finest trowel. The labor of their construction was appalling. Brick had to be burnt, stone quarried and dressed with crude tools, and huge timbers for rafters brought on men's shoulders from the mountain forests, sometimes thirty miles distant, through rocky canyons and over trackless hills. The Indians performed most of this labor and did their work well, but the ravages of a century have been severe and save only a few, preserved by reverend hands, where modern worshippers still kneel and recite their orisons, the venerable ruins are forsaken by all except the tourist and antiquarian, and their bells are silent forever.

ROOFING WITH THE STEEL SQUARE—No. 5. HIP AND VALLEY ROOFS

By J. H. B.

THE two photographs herewith show two methods of forming a "valley" in a roof, the term "valley" being used to describe the gutter, which is inevitable when two roofs run into one another at right angles. Figure 36 shows the proper way of forming a valley, and this is shown in plan in Figure 37, while Figure 38 shows the plan of the plates which carry the rafters.

The valley rafters are those which spring from the angle of the two plates, as at A, and fit into the angles formed by the two ridges, as at B, thus appearing very like hips, with the exception that they form what may be called an internal angle in the roof instead of an external angle. As a rule, no foot is required on a valley rafter, the two nearest common rafters usually coming near enough to the angle to carry facia and soffit; but, like all other rules, this has exceptions, and feet are sometimes required on the valley rafters. The method of obtaining the correct length of the valleys is identical with that described in the previous article for the hips, but if feet are required these must be taken into con-

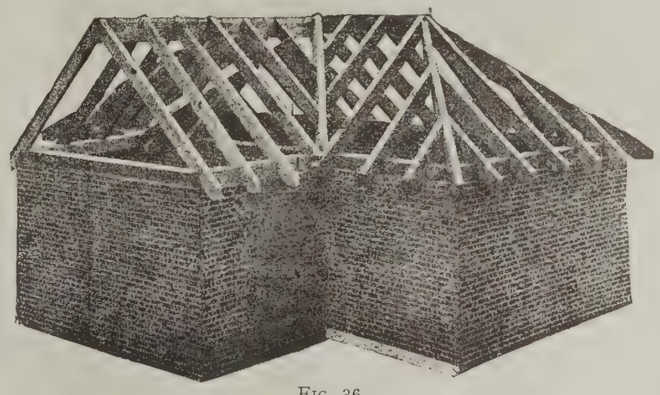

FIG. 36.

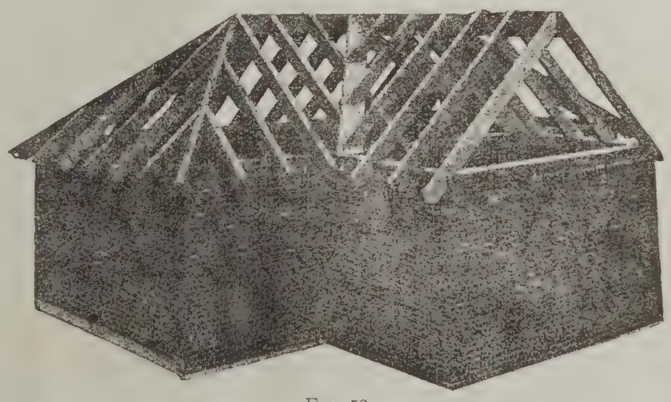
sideration, and even if not it must not be forgotten that the back of the valley must run over the edge of the plate. Thus, in Figure 39 the mark C is the backing, but the rafter must continue as shown.

Properly speaking, a center line down the back of the valleys should be in the same plane as the rest of the roof, but in practice the edges of the valley are brought level and the gutter boards get over the rest, as in Figure 40. This shows that, theoretically, the back of the valley should be as dotted lines, but as in the hips the back is rarely beveled, as in the valley the backs are left straight. In the same way, if a foot is used on a valley rafter, as Figure 41, it is not cut out straight with the roof each way, forming a notch, but straight across the angle. The top ends of the valleys are cut exactly as the hips, the same rules applying for obtaining the correct angles as well as for the lengths.

As regards the short rafters which come to the valley rafters each way, the lengths of these, as well as the bevels, are obtained



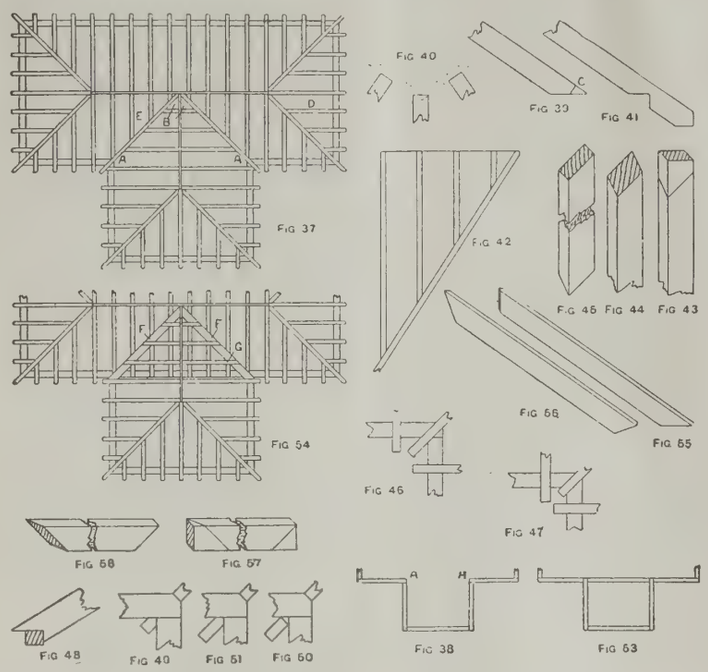


FIG. 52.
